(54) Title: METHODS AND MEANS FOR INHIBITION OF CDK4 ACTIVITY

(57) Abstract

p21WAF1 interacts with cyclin D1 and Cdk4. Peptide fragments of p21 inhibit the interaction and/or affect Cdk4 activity. The peptides, derivative peptides and non-peptidyl mimetics thereof are useful in affecting activity of Cdk4, such as RB phosphorylation, and cellular proliferation, indicative of therapeutic usefulness in treatment of tumours and other hyperproliferative disorders. Assay and screening methods allow identification of such modulators, especially inhibitors, of Cdk4 activity.

1

METHODS AND MEANS FOR INHIBITION OF CDK4 ACTIVITY

present invention relates to substances and their therapeutic use, and in particular to the identification of 5 regions of p21WAF1 that bind to cyclin dependent kinases, specifically Cdk4, and/or cyclin D1, and to substances, fragments and mimetics based on this region. The present invention also relates to pharmaceutical compositions comprising these molecules and their use in therapeutic applications for 10 treating hyperproliferative disorders, such as cancer and psoriasis, and compositions comprising these molecules and their use in applications relating to growth in eukaryotic cells. invention also relates to assay methods and means for identifying substances useful for interfering with 15 p21/Cdk4/cyclin interaction, and preferably inhibiting Cdk4 activity.

The tumour suppressor function of p53 is linked to a DNA-damage inducible cell cycle checkpoint pathway (Kastan et al., 1991), 20 in which p53 can induce either growth arrest (Agarwal et al., 1995) or apoptosis (Clarke et al., 1993; Lowe et al., 1993; Merritt et al., 1994) in the damaged cells. The biochemical activity of p53 most tightly associated with tumour suppression and growth arrest involves an ionising radiation-dependent activation of sequence-specific transcriptional activity (Kastan et al., 1991; Lu and Lane, 1993; Pietenpol, et al., 1994). p53 induces the transcription of a number of genes, the products of which play a direct role in mediating growth arrest. These

2

p53-inducible negative regulators of cell proliferation include: the cyclin dependent kinase inhibitor (CKI), p21WAF1 (El-Deiry et al., 1993; Harper et al., 1993; Xiong et al., 1993; Gu et al., 1993); an apoptosis promoting protein, Bax (Miyashita and Reed, 1995); the insulin growth factor binding protein IGF-BP3 (Buckbinder et al., 1995); and Gadd45 (Kastan et al., 1992), a potent inhibitor of cell proliferation with an as yet unclear biochemical function (Kearsey et al., 1995).

10 A common event in the development of human neoplasia is the inactivation of a DNA damage-inducible cell cycle checkpoint pathway regulated by p53 (Hollstein et al.,1991; Lane, 1992; Agrawal et al., 1995). A variety of mechanisms can lead to the functional inactivation of the p53 pathway, including: missense 15 mutations within, or deletions of the p53 gene, inactivation of wild type p53 protein function by interaction with the oncogenic cellular protein mdm-2 (Momand et al., 1992), or the inability to induce downstream effector molecules, such as p21 WAF1 (Deng

et al., 1995; Waldman et al., 1995).

20

Our growing knowledge of the molecular mechanisms underlying the transformation of mammalian cells offers the opportunity to create rationally designed inhibitors of specific biochemical processes essential to uncontrolled cell proliferation or cancer. Recent developments have shown that the reactivation of the p53 pathway in some human tumours could in theory be achieved by: (i) activating the biochemical function of mutant p53 protein (Halazonetis and Kandil, 1993; Hupp et al., 1993),

3

possibly using small peptides as leads for drug design (Hupp et al., 1995); (ii) disrupting the interaction of the oncogene mdm-2 and wild type p53 through the use of peptide-mimetic inhibitors of complex formation (Picksley et al., 1994); (iii) restoring or mimicking the function of the downstream effector molecule p21^{WAF1}, which on its own is capable of mediating growth suppression (El-Deiry et al., 1993; Eastham et al., 1995).

- 10 p21WAF1 is an inhibitor of both the G1 cyclin dependent protein kinases (CDKs; which control the progression from G1 into S phase) (Harper et al., 1995) and proliferating cell nuclear antigen (PCNA; an essential DNA-replication factor) (Florez-Rozas et al., 1994; Waga et al., 1994). Thus,
- 15 inhibition of the function of either CDKs or PCNA provides, in theory, two distinct avenues for development of drug discovery programmes which are based on the activity of p21^{WAF1}. The PCNA binding function of p21^{WAF1} can be mimicked by a 20-amino acid peptide derived from the C-terminal domain of p21^{WAF1} and
- 20 this peptide is sufficient to partially inhibit SV40 replication in vitro (Warbrick et al., 1995).

Despite its PCNA binding role, the primary function of the p21^{WAF1} protein as a growth suppressor appears to be inhibition 25 of the G1 cyclin-CDK complexes (Chen et al., 1995; Harper et al., 1995; Luo et al., 1995; Nakanishi et al., 1995b). Luo et al. (1995) reported the N-terminal domain of p21, composed of residues 1-75, to act as a CDK-inhibitor in vitro, inhibiting

4

cyclin E-Cdk2.

The present invention concerns (i) the elucidation of the molecular mechanism of cyclin D1-Cdk4 complex inhibition by 5 p21^{WAF1}, and (ii) the identification of peptide mimetics of p21^{WAF1} inhibitory activity, through the examination of the binding and inhibitory properties of a series of synthetic peptides based on the amino acid sequence of p21^{WAF1}. Our studies found that two peptides derived from the N-terminal 10 domain of p21^{WAF1} have biochemical activity; a peptide 4 (residues 46-65) forms a stable complex with Cdk4, but has no inhibitory activity, while a peptide 2 (residues 16-35) binds to cyclin D1 and inhibits Cdk4 activity with a 10.5 of 2 μM.

15 These data define for a cyclin binding site on p21^{WAF1} and suggest that one mechanism involved in the CDK inhibitory action of p21^{WAF1} employs binding to the cyclin subunit of the CDK holoenzyme. This has lead us to propose that p21^{WAF1} can inhibit Cdk4 activity allosterically through conformational or (ii) interfering with the cyclin-Cdk interaction or (iii) interfering with the cyclin-Cdk-substrate interaction changes in the structure of cyclin D1. Furthermore, peptides based on the C-terminal sequence of p21^{WAF1} interact with both cyclin D1 and Cdk4, and are potent inhibitors of Cdk4 activity, with a 25 peptide (peptide 10 herein) composed of residues 141-160 having an I_{0.5} of 0.1 μM. We show that both of the inhibitory peptides bind at physiologically relevant sites on cyclin D1 and/or Cdk4, and that they display specificity mimicking that of full length

5

p21^{WAF1}. Importantly, the potency of the C-terminal peptide is improved by making a single amino acid substitution (D - A at position 149). We have mapped the inhibitory component of this peptide using alanine mutation analysis and show that it is distinct from the PCNA interaction domain, which also resides in the C-terminal region of the p21^{WAF1} protein.

Remarkably, a stretch of just five amino acids contains the Cdk4 inhibitory motif and a single conservative mutation at either of two hydrophobic amino acid residues completely abolishes the inhibitory activity of the peptide. These data have exciting implications for the mechanism of action of p21WAF1 protein and represent a starting point for a drug design programme aimed at producing synthetic molecules functioning as tumour suppressors downstream of p53.

Accordingly, in one aspect, the present invention provides a substance which has the property of inhibiting Cdk4, said substance comprising:

- 20 (i) a peptide fragment consisting of the motif xyLzF, wherein y and z are any amino acid and x is preferably R, or a derivative of said peptide fragment; or,
 - (ii) a functional mimetic of said peptide fragment.
- 25 In a further aspect, the present invention provides the above substance for use in a method of medical treatment.

In a further aspect, the present invention provides the use of

6

a substance which has the property of inhibiting Cdk4 in the preparation of a medicament for the treatment of a hyperproliferative disorder, said substance comprising:

- (i) fragment of the C-terminal portion of p21WAF1, or an 5 active portion or derivative thereof; or,
 - (ii) a peptide fragment including the motif xyLzF, wherein y and z are any amino acid and x is preferably R, or a derivative of said peptide fragment; or,
 - (iii) a functional mimetic of (i) or (ii).

10

In a preferred embodiment, the C-terminal portion of $p21^{WAF1}$ consisting of the peptide motif KRRLIFSK was found to completely inhibit cyclin-Cdk4 activity and to prevent phosphorylation of pRb (see figure 6).

15

In a further aspect, the present invention provides a substance which has the property of binding to Cdk4 for use in a method of medical treatment, said substance comprising:

- (i) a fragment of the p21^{WAF1} protein consisting of
 20 residues 46-65 of the p21^{WAF1} amino acid sequence, or an active portion or derivative thereof; or,
 - (ii) a functional mimetic of said fragment.

In a further aspect, the present invention provides the use of 25 a substance which has the property of binding Cdk4 in the preparation of a medicament for the treatment of a hyperproliferative disorder, said substance comprising:

(i) a fragment of the $p21^{WAF1}$ protein consisting of

7

residues 46-65 of the $p21^{WAF1}$ amino acid sequence, or an active portion or derivative thereof; or,

- (ii) a functional mimetic of said fragment.
- 5 In a further aspect, the present invention provides a substance which has the properties of binding cyclin D and/or inhibiting Cdk4 for use in a method of medical treatment, said substance comprising:
- 10 (i) a fragment of the $p21^{WAF1}$ protein consisting of residues 16-35 of the $p21^{WAF1}$ amino acid sequence, or an active portion or derivative thereof; or,
 - (ii) a functional mimetic of said fragment.
- 15 In a further aspect, the present invention provides the use of a substance which has the property of binding cyclin D1 and/or inhibiting Cdk4 in the preparation of a medicament for the treatment of a hyperproliferative disorder, said substance comprising:
- 20 (i) a fragment of the p21^{WAF1} protein consisting of residues 16-35 of the p21^{WAF1} amino acid sequence, or an active portion or derivative thereof; or,
 - (ii) a functional mimetic of said peptide fragment.
- 25 Based on experimental evidence included below showing residues involved in binding of peptide 2 (residues 16-35), and the crystal structure available for p27 (related to p21), the following general formula for peptides useful in accordance with

8

various aspects of the present invention is provided:

KxxRRyFzP

5 wherein x may be any amino acid, y and z may be hydrophobic, and each of the underlined residues may be absent or different, i.e. another amino acid. Hydrophobic residues may be alanine, valine, leucine, isoleucine, proline, phenylalanine, tryptophan, methionine. Either or both of the amino acids R may be 10 substituted by other basic residues, particularly lysine (K) or histidine (H).

In the present invention, "an active portion" means a peptide which is less than the fragment of the p21WAF1 amino acid sequence, but which retains the relevant property mentioned above.

In the present invention, "functional mimetic" means a substance which may not contain an active portion of the p21WAF1 amino 20 acid sequence and is probably not a peptide at all, but which has the relevant property mentioned above.

In the present invention, "a derivative" means a peptide modified by varying its amino acid sequence, eg by manipulation of the nucleic acid encoding the peptide or by altering the peptide itself. Such derivatives of the natural amino acid sequence may involve insertion, addition, deletion or substitution of one or more amino acids, without fundamentally

9

altering the essential activity of the peptides. An example of a derivative is the p21WAF1 mutant in which A was substituted for D at position 149 of the full length protein, this mutant having enhanced cyclin D1-Cdk4 inhibitory activity.

5

Preferred substances according to certain embodiments of the present invention do not bind PCNA, and/or do not interfere with p21 interaction or binding with PCNA.

10 Cell cycle arrest may be induced by various aspects according to the present invention in Rb negative and/or Rb positive cells, as exemplified experimentally below.

In a further aspect, the present invention provides
15 pharmaceutical compositions comprising one or more of the above substances in combination with a pharmaceutically acceptable carrier.

- In a further aspect, the present invention relates to 20 compositions comprising one or more of the above substances and their use in controlling the growth of eukaryotic cells, eg as a food preservative or as an agent to promote the growth of plants.
- 25 In a further aspect, the present invention provides compounds comprising any of the above substances coupled to carrier molecules, enabling the compounds to be delivered to cells in vivo. In one embodiment, the carrier molecule is a 16 aa

10

peptide sequence derived from the homeodomain of Antennapedia (e.g. as sold under the name "Penetratin") which can be coupled to one of the above substances via a terminal Cys residue. Alternatively, as in the examples described below, a carrier peptide (having the sequence RQIKIWFQNRRMKWKK) can be synthesised so it is directly attached to peptide fragments. The "Penetratin" molecule and its properties are described in WO91/18981.

10 Thus, the present invention in various aspects provides for interfering with or interrupting interaction between p21 and cyclin D1 and/or Cdk4 using an appropriate agent.

Such an agent may be capable of blocking binding between a site 15 located at amino acid residues identified herein as being involved in and/or important for binding or interaction with cyclin D1 and/or Cdk4.

The full sequence of the p21 protein has been elucidated and is 20 set out in WO95/13375, WO93/12251 and WO95/06415 which are incorporated herein by reference.

Such agents may be identified by screening techniques which involve determining whether an agent under test inhibits or 25 disrupts the binding of p21 protein or a suitable fragment, derivative, analogue or functional mimetic thereof, with cyclin D1 and/or Cdk4, or a relevant fragment, derivative, analogue or functional mimetic thereof.

11

Suitable fragments of p21 include those which include residues as identified herein. Smaller fragments, and derivatives, analogues and functional mimetics of this fragment may similarly be employed, e.g. peptides identified using a technique such as alanine scanning.

In a further aspect of the invention, whereas assays using the peptides described herein and the use of the peptides are described in the context of modulating the interaction of p21 10 with cyclin D1 and/or Cdk4, these peptides may also be useful as p21 mimetics to inhibit the interaction of p21 and other cyclin-Cdk interactions, particularly G1 complexes such as cyclin E-Cdk2. Thus the various described embodiments of the invention above and below herein with regard to cyclin D1 and/or 15 Cdk4 is applicable mutatis mutandis to these other cyclins and/or Cdks respectively.

Screening methods and assays are discussed in further detail below.

20

One class of agents that can be used to disrupt the binding of p21 and cyclin D1 and/or Cdk 4 are peptides based on the sequence motifs of p21 that interact with cyclin D1 and/or Cdk4. Such peptides tend to be small molecules, and may be about 40 amino acids in length or less, preferably about 35 amino acids in length or less, more preferably about 30 amino acids in length, or less, more preferably about 25 amino acids or less, more preferably about 25 amino acids or less,

12

about 15 amino acids or less, more preferably about 10 amino acids or less, or 9, 8, 7, 6 5 or less in length. The present invention also encompasses peptides which are sequence variants or derivatives of a wild type p21 sequence.

5

Preferably, the amino acid sequence shares homology with a fragment of the relevant p21 fragment sequence shown preferably at least about 30%, or 40%, or 50%, or 60%, or 70%, or 75%, or 80%, or 85% homology, or at least about 90% or 95% homology.

10 Thus, a peptide fragment of p21 may include 1, 2, 3, 4, 5, greater than 5, or greater than 10 amino acid alterations such as substitutions with respect to the wild-type sequence.

A derivative of a peptide for which the specific sequence is disclosed herein may be in certain embodiments the same length or shorter than the specific peptide. In other embodiments the peptide sequence or a variant thereof may be included in a larger peptide, as discussed above, which may or may not include an additional portion of p21. 1, 2, 3, 4 or 5 or more additional amino acids, adjacent to the relevant specific peptide fragment in p21, or heterologous thereto may be included at one end or both ends of the peptide.

As is well-understood, homology at the amino acid level is 25 generally in terms of amino acid similarity or identity. Similarity allows for "conservative variation", i.e. substitution of one hydrophobic residue such as isoleucine, valine, leucine or methionine for another, or the substitution

13

of one polar residue for another, such as arginine for lysine, glutamic for aspartic acid, or glutamine for asparagine. Similarity may be as defined and determined by the TBLASTN program, of Altschul et al. (1990) J. Mol. Biol. 215: 403-10, which is in standard use in the art. Homology may be over the full-length of the relevant peptide or over a contiguous sequence of about 5, 10, 15, 20, 25, 30 or 35 amino acids, compared with the relevant wild-type amino acid sequence.

10 As noted, variant peptide sequences and peptide and non-peptide analogues and mimetics may be employed, as discussed further below.

Various aspects of the present invention provide a substance,

15 which may be a single molecule or a composition including two
or more components, which includes a peptide fragment of p21
which includes a sequence as recited above and/or disclosed
elsewhere herein, a peptide consisting essentially of such a
sequence, a peptide including a variant, derivative or analogue

20 sequence, or a non-peptide analogue or mimetic which has the
ability to bind cyclin D1 and/or Cdk4 and/or disrupt or
interfere with interaction between p21 and cyclin D1 and/or Cdk
4.

25 Variants include peptides in which individual amino acids can be substituted by other amino acids which are closely related as is understood in the art and indicated above.

14

Non-peptide mimetics of peptides are discussed further below.

As noted, a peptide according to the present invention and for use in various aspects of the present invention may include or 5 consist essentially of a fragment of p21 as disclosed, such as a fragment whose sequence is given above. Where one or more additional amino acids are included, such amino acids may be from p21 or may be heterologous or foreign to p21. A peptide may also be included within a larger fusion protein, 10 particularly where the peptide is fused to a non-p21 (i.e. heterologous or foreign) sequence, such as a polypeptide or protein domain.

The invention also includes derivatives of the peptides, 15 including the peptide linked to a coupling partner, e.g. an effector molecule, a label, a drug, a toxin and/or a carrier or transport molecule. Techniques for coupling the peptides of the invention to both peptidyl and non-peptidyl coupling partners are well known in the art. In one embodiment, the carrier 20 molecule is a 16 aa peptide sequence derived from the homeodomain of Antennapedia (e.g. as sold under the name "Penetratin"), which can be coupled to a peptide via a terminal Cys residue. The "Penetratin" molecule and its properties are described in WO 91/18981.

25

Peptides may be generated wholly or partly by chemical synthesis. The compounds of the present invention can be readily prepared according to well-established, standard liquid

WO 97/42222

15

PCT/GB97/01250

or, preferably, solid-phase peptide synthesis methods, general descriptions of which are broadly available (see, for example, in J.M. Stewart and J.D. Young, Solid Phase Peptide Synthesis, 2nd edition, Pierce Chemical Company, Rockford, Illinois (1984),

- 5 in M. Bodanzsky and A. Bodanzsky, The Practice of Peptide Synthesis, Springer Verlag, New York (1984); and Applied Biosystems 430A Users Manual, ABI Inc., Foster City, California), or they may be prepared in solution, by the liquid phase method or by any combination of solid-phase, liquid phase
- 10 and solution chemistry, e.g. by first completing the respective peptide portion and then, if desired and appropriate, after removal of any protecting groups being present, by introduction of the residue X by reaction of the respective carbonic or sulfonic acid or a reactive derivative thereof.

15

Another convenient way of producing a peptidyl molecule according to the present invention (peptide or polypeptide) is to express nucleic acid encoding it, by use of nucleic acid in an expression system.

20

Accordingly the present invention also provides in various aspects nucleic acid encoding the polypeptides and peptides of the invention.

25 Generally, nucleic acid according to the present invention is provided as an isolate, in isolated and/or purified form, or free or substantially free of material with which it is naturally associated, such as free or substantially free of

16

nucleic acid flanking the gene in the human genome, except possibly one or more regulatory sequence(s) for expression. Nucleic acid may be wholly or partially synthetic and may include genomic DNA, cDNA or RNA. Where nucleic acid according to the invention includes RNA, reference to the sequence shown should be construed as reference to the RNA equivalent, with U substituted for T.

Nucleic acid sequences encoding a polypeptide or peptide in 10 accordance with the present invention can be readily prepared by the skilled person using the information and references contained herein and techniques known in the art (for example, see Sambrook, Fritsch and Maniatis, "Molecular Cloning, A Laboratory Manual, Cold Spring Harbor Laboratory Press, 1989, 15 and Ausubel et al, Short Protocols in Molecular Biology, John Wiley and Sons, 1992), given the nucleic acid sequence and clones available. These techniques include (i) the use of the polymerase chain reaction (PCR) to amplify samples of such nucleic acid, e.g. from genomic sources, (ii) chemical 20 synthesis, or (iii) preparing cDNA sequences. DNA encoding p21 fragments may be generated and used in any suitable way known to those of skill in the art, including by taking encoding DNA, identifying suitable restriction enzyme recognition sites either side of the portion to be expressed, and cutting out said 25 portion from the DNA. The portion may then be operably linked to a suitable promoter in a standard commercially available expression system. Another recombinant approach is to amplify the relevant portion of the DNA with suitable PCR primers.

17

Modifications to the p21 sequences can be made, e.g. using site directed mutagenesis, to lead to the expression of modified p21 peptide or to take account of codon preference in the host cells used to express the nucleic acid.

5

In order to obtain expression of the nucleic acid sequences, the sequences can be incorporated in a vector having one or more control sequences operably linked to the nucleic acid to control its expression. The vectors may include other sequences such 10 as promoters or enhancers to drive the expression of the inserted nucleic acid, nucleic acid sequences so that the polypeptide or peptide is produced as a fusion and/or nucleic acid encoding secretion signals so that the polypeptide produced in the host cell is secreted from the cell. Polypeptide can 15 then be obtained by transforming the vectors into host cells in which the vector is functional, culturing the host cells so that the polypeptide is produced and recovering the polypeptide from the host cells or the surrounding medium. Prokaryotic and eukaryotic cells are used for this purpose in the art, including 20 strains of E. coli, yeast, and eukaryotic cells such as COS or CHO cells.

Thus, the present invention also encompasses a method of making a polypeptide or peptide (as disclosed), the method including expression from nucleic acid encoding the polypeptide or peptide (generally nucleic acid according to the invention). This may conveniently be achieved by growing a host cell in culture, containing such a vector, under appropriate conditions which

18

cause or allow expression of the polypeptide. Polypeptides and peptides may also be expressed in in vitro systems, such as reticulocyte lysate.

- 5 Systems for cloning and expression of a polypeptide in a variety of different host cells are well known. Suitable host cells include bacteria, eukaryotic cells such as mammalian and yeast, and baculovirus systems. Mammalian cell lines available in the art for expression of a heterologous polypeptide include Chinese 10 hamster ovary cells, HeLa cells, baby hamster kidney cells, COS cells and many others. A common, preferred bacterial host is E. coli.
- Suitable vectors can be chosen or constructed, containing 15 appropriate regulatory sequences, including promoter sequences, terminator fragments, polyadenylation sequences, enhancer sequences, marker genes and other sequences as appropriate. Vectors may be plasmids, viral e.g. 'phage, or phagemid, as appropriate. For further details see, for example, Molecular 20 Cloning: a Laboratory Manual: 2nd edition, Sambrook et al., 1989, Cold Spring Harbor Laboratory Press. Many known techniques and protocols for manipulation of nucleic acid, for example in preparation of nucleic acid constructs, mutagenesis, sequencing, introduction of DNA into cells and gene expression, 25 and analysis of proteins, are described in detail in Current
- Protocols in Molecular Biology, Ausubel et al. eds., John Wiley & Sons, 1992.

19

Thus, a further aspect of the present invention provides a host cell containing heterologous nucleic acid as disclosed herein.

The nucleic acid of the invention may be integrated into the 5 genome (e.g. chromosome) of the host cell. Integration may be promoted by inclusion of sequences which promote recombination with the genome, in accordance with standard techniques. The nucleic acid may be on an extra-chromosomal vector within the cell, or otherwise identifiably heterologous or foreign to the 10 cell.

A still further aspect provides a method which includes introducing the nucleic acid into a host cell. The introduction, which may (particularly for in vitro introduction)

- be generally referred to without limitation as "transformation", may employ any available technique. For eukaryotic cells, suitable techniques may include calcium phosphate transfection, DEAE-Dextran, electroporation, liposome-mediated transfection and transduction using retrovirus or other virus, e.g. vaccinia
- 20 or, for insect cells, baculovirus. For bacterial cells, suitable techniques may include calcium chloride transformation, electroporation and transfection using bacteriophage. As an alternative, direct injection of the nucleic acid could be employed.

25

Marker genes such as antibiotic resistance or sensitivity genes may be used in identifying clones containing nucleic acid of interest, as is well known in the art.

20

The introduction may be followed by causing or allowing expression from the nucleic acid, e.g. by culturing host cells (which may include cells actually transformed although more likely the cells will be descendants of the transformed cells)

5 under conditions for expression of the gene, so that the encoded polypeptide (or peptide) is produced. If the polypeptide is expressed coupled to an appropriate signal leader peptide it may be secreted from the cell into the culture medium. Following production by expression, a polypeptide or peptide may be 10 isolated and/or purified from the host cell and/or culture medium, as the case may be, and subsequently used as desired, e.g. in the formulation of a composition which may include one or more additional components, such as a pharmaceutical composition which includes one or more pharmaceutically acceptable excipients, vehicles or carriers (e.g. see below).

Introduction of nucleic acid encoding a peptidyl molecule according to the present invention may take place in vivo by way of gene therapy, to disrupt or interfere with interaction 20 between p21 and cyclin D1 and/or ckd4.

Thus, a host cell containing nucleic acid according to the present invention, e.g. as a result of introduction of the nucleic acid into the cell or into an ancestor of the cell 25 and/or genetic alteration of the sequence endogenous to the cell or ancestor (which introduction or alteration may take place in vivo or ex vivo), may be comprised (e.g. in the soma) within an organism which is an animal, particularly a mammal, which may

21

be human or non-human, such as rabbit, guinea pig, rat, mouse or other rodent, cat, dog, pig, sheep, goat, cattle or horse, or which is a bird, such as a chicken. Genetically modified or transgenic animals or birds comprising such a cell are also provided as further aspects of the present invention.

This may have a therapeutic aim. (Gene therapy is discussed below.) Also, the presence of a mutant, allele, derivative or variant sequence within cells of an organism, particularly when 10 in place of a homologous endogenous sequence, may allow the organism to be used as a model in testing and/or studying substances which modulate activity of the encoded polypeptide in vitro or are otherwise indicated to be of therapeutic potential. Conveniently, however, assays for such substances 15 may be carried out in vitro, within host cells or in cell-free systems.

Suitable screening methods are conventional in the art. They include techniques such as radioimmunosassay, scintillation 20 proximetry assay and ELISA methods. Suitably either the p21 protein or fragment or cyclinD1 and/or Cdk 4 or fragment, or an analogue, derivative, variant or functional mimetic thereof, is immobilised whereupon the other is applied in the presence of the agents under test. In a scintillation proximetry assay a 25 biotinylated protein fragment is bound to streptavidin coated scintillant - impregnated beads (produced by Amersham). Binding of radiolabelled peptide is then measured by determination of radioactivity induced scintillation as the radioactive peptide

22

binds to the immobilized fragment. Agents which intercept this are thus inhibitors of the interaction.

In one general aspect, the present invention provides an assay 5 method for a substance with ability to disrupt interaction or binding between p21 and cyclin D1 and/or Cdk4, the method including:

- (a) bringing into contact a substance according to the invention including a peptide fragment of p21 or a derivative,
- 10 variant or analogue thereof as disclosed, a substance including the relevant fragment of cyclin Dl and/or Cdk4 or a variant, derivative or analogue thereof, and a test compound, under conditions wherein, in the absence of the test compound being an inhibitor of interaction or binding of said substances, said
 - (b) determining interaction or binding between said substances.

15 substances interact or bind; and

A test compound which disrupts, reduces, interferes with or wholly or partially abolishes binding or interaction between 20 said substances (e.g. including a p21 fragment and including a cyclin D1 and/or Cdk 4 fragment), and which may modulate Cdk4 activity, may thus be identified.

Another general aspect of the present invention provides an 25 assay method for a substance able to bind the relevant region of p21 as the case may be, the method including:

(a) bringing into contact a substance which includes a peptide fragment of p21 which interacts with cyclin D1 and/or Cdk 4 as

23

disclosed, or a variant, derivative or analogue thereof as disclosed, and a test compound; and

(b) determining binding between said substance and the test compound.

5

A test compound found to bind to the relevant portion of p21 may be tested for ability to disrupt p21 interaction or binding with cyclin D1 and/or Cdk 4 and/or ability to affect Cdk4 activity or other activity mediated by p21 as discussed already above.

10

Performance of an assay method according to the present invention may be followed by isolation and/or manufacture and/or use of a compound, substance or molecule which tests positive for ability to interfere with interaction between p21 and cyclin 15 D1 and/or Cdk4 and/or inhibit p21-mediated Cdk4 activity.

The precise format of an assay of the invention may be varied by those of skill in the art using routine skill and knowledge. For example, interaction between substances may be studied in 20 vitro by labelling one with a detectable label and bringing it into contact with the other which has been immobilised on a solid support. Suitable detectable labels, especially for petidyl substances include 35S-methionine which may be incorporated into recombinantly produced peptides and 25 polypeptides. Recombinantly produced peptides and polypeptides may also be expressed as a fusion protein containing an epitope which can be labelled with an antibody.

24

The protein which is immobilized on a solid support may be immobilized using an antibody against that protein bound to a solid support or via other technologies which are known per se. A preferred in vitro interaction may utilise a fusion protein 5 including glutathione-S-transferase (GST). This may be immobilized on glutathione agarose beads. In an in vitro assay format of the type described above a test compound can be assayed by determining its ability to diminish the amount of labelled peptide or polypeptide which binds to the immobilized 10 GST-fusion polypeptide. This may be determined by fractionating the glutathione-agarose beads by SDS-polyacrylamide gel electrophoresis. Alternatively, the beads may be rinsed to remove unbound protein and the amount of protein which has bound can be determined by counting the amount of label present in, 15 for example, a suitable scintillation counter.

An assay according to the present invention may also take the form of an *in vivo* assay. The *in vivo* assay may be performed in a cell line such as a yeast strain or mammalian cell line in 20 which the relevant polypeptides or peptides are expressed from one or more vectors introduced into the cell.

The ability of a test compound to disrupt interaction or binding between p21 and cyclin D1 and/or Cdk4 may be determined using 25 a so-called two-hybid assay.

For example, a polypeptide or peptide containing a fragment of p21 or cyclin D1/Cdk4 as the case may be, or a peptidyl analogue

25

or variant thereof as disclosed, may be fused to a DNA binding domain such as that of the yeast transcription factor GAL 4. The GAL 4 transcription factor includes two functional domains. These domains are the DNA binding domain (GAL4DBD) and the GAL4 5 transcriptional activation domain (GAL4TAD). By fusing one polypeptide or peptide to one of those domains and another polypeptide or peptide to the respective counterpart, a functional GAL 4 transcription factor is restored only when two polypeptides or peptides of interest interact. 10 interaction of the polypeptides or peptides may be measured by the use of a reporter gene probably linked to a GAL 4 DNA binding site which is capable of activating transcription of said reporter gene. This assay format is described by Fields and Song, 1989, Nature 340; 245-246. This type of assay format 15 can be used in both mammalian cells and in yeast. combinations of DNA binding domain and transcriptional activation domain are available in the art and may be preferred, such as the LexA DNA binding domain and the VP60 transcriptional activation domain.

20

To take a Lex/VP60 two hybrid screen by way of example for the purpose of illustration, yeast or mammalian cells may be transformed with a reporter gene construction which expresses a selective marker protein (e.g. encoding β -galactosidase or luciferase). The promoter of that gene is designed such that it contains binding site for the LexA DNA-binding protein. Gene expression from that plasmid is usually very low. Two more expression vectors may be transformed into the yeast containing

26

the selectable marker expression plasmid, one containing the coding sequence for the full length LexA gene linked to a multiple cloning site. This multiple cloning site is used to clone a gene of interest, i.e. encoding a p21 or cyclinD1/Cdk4 polypeptide or peptide in accordance with the present invention, in frame on to the LexA coding region. The second expression vector then contains the activation domain of the herpes simplex transactivator VP16 fused to a test peptide sequence or more preferably a library of sequences encoding peptides with diverse e.g. random sequences. Those two plasmids facilitate expression from the reporter construct containing the selectable marker only when the LexA fusion construct interacts with a polypeptide or peptide sequence derived from the peptide library.

15 A modification of this when looking for peptides or other substances which interfere with interaction between a p21 polypeptide or peptide and an cyclin D1/Cdk 4 polypeptide or peptide, employs the p21 or cyclin D1/Cdk4 polypeptide or peptide as a fusion with the LexA DNA binding domain, and the counterpart cyclin D1/Cdk4 or p21 polypeptide or peptide as a fusion with VP60, and involves a third expression cassette, which may be on a separate expression vector, from which a peptide or a library of peptides of diverse and/or random sequence may be expressed. A reduction in reporter gene expression (e.g. in the case of β-galactosidase a weakening of the blue colour) results from the presence of a peptide which disrupts the p21/cyclinD1 and/or Cdk4 interaction, which interaction is required for transcriptional activation of the

27

 β -galactosidase gene. Where a test substance is not peptidyl and may not be expressed from encoding nucleic acid within a said third expression cassette, a similar system may be employed with the test substance supplied exogenously.

5

As noted, instead of using LexA and VP60, other similar combinations of proteins which together form a functional transcriptional activator may be used, such as the GAL4 DNA binding domain and the GAL4 transcriptional activation domain.

10

When performing a two hybrid assay to look for substances which interfere with the interaction between two polypeptides or peptides it may be preferred to use mammalian cells instead of yeast cells. The same principles apply and appropriate methods are well known to those skilled in the art.

The amount of test substance or compound which may be added to an assay of the invention will normally be determined by trial and error depending upon the type of compound used. Typically,

20 from about 0.01 to 100 nM concentrations of putative inhibitor compound may be used, for example from 0.1 to 10 nM. Greater concentrations may be used when a peptide is the test substance.

Compounds which may be used may be natural or synthetic chemical compounds used in drug screening programmes. Extracts of plants which contain several characterised or uncharacterised components may also be used.

28

Antibodies directed to the site of interaction in either protein form a further class of putative inhibitor compounds. Candidate inhibitor antibodies may be characterised and their binding regions determined to provide single chain antibodies and fragments thereof which are responsible for disrupting the interaction.

Antibodies may be obtained using techniques which are standard in the art. Methods of producing antibodies include immunising 10 a mammal (e.g. mouse, rat, rabbit, horse, goat, sheep or monkey) with the protein or a fragment thereof. Antibodies may be obtained from immunised animals using any of a variety of techniques known in the art, and screened, preferably using binding of antibody to antigen of interest. For instance, 15 Western blotting techniques or immunoprecipitation may be used (Armitage et al., 1992, Nature 357: 80-82). Isolation of antibodies and/or antibody-producing cells from an animal may be accompanied by a step of sacrificing the animal.

20 As an alternative or supplement to immunising a mammal with a peptide, an antibody specific for a protein may be obtained from a recombinantly produced library of expressed immunoglobulin variable domains, e.g. using lambda bacteriophage or filamentous bacteriophage which display functional immunoglobulin binding domains on their surfaces; for instance see WO92/01047. The library may be naive, that is constructed from sequences obtained from an organism which has not been immunised with any of the proteins (or fragments), or may be one constructed using

29

sequences obtained from an organism which has been exposed to the antigen of interest.

Antibodies according to the present invention may be modified 5 in a number of ways. Indeed the term "antibody" should be construed as covering any binding substance having a binding domain with the required specificity. Thus the invention covers antibody fragments, derivatives, functional equivalents and homologues of antibodies, including synthetic molecules and 10 molecules whose shape mimicks that of an antibody enabling it to bind an antigen or epitope.

Example antibody fragments, capable of binding an antigen or other binding partner are the Fab fragment consisting of the VL, 15 VH, Cl and CH1 domains; the Fd fragment consisting of the VH and CH1 domains; the Fv fragment consisting of the VL and VH domains of a single arm of an antibody; the dAb fragment which consists of a VH domain; isolated CDR regions and F(ab')2 fragments, a bivalent fragment including two Fab fragments linked by a 20 disulphide bridge at the hinge region. Single chain Fv fragments are also included.

A hybridoma producing a monoclonal antibody according to the present invention may be subject to genetic mutation or other changes. It will further be understood by those skilled in the art that a monoclonal antibody can be subjected to the techniques of recombinant DNA technology to produce other antibodies or chimeric molecules which retain the specificity

30

of the original antibody. Such techniques may involve introducing DNA encoding the immunoglobulin variable region, or the complementarity determining regions (CDRs), of an antibody to the constant regions, or constant regions plus framework regions, of a different immunoglobulin. See, for instance, EP184187A, GB 2188638A or EP-A-0239400. Cloning and expression of chimeric antibodies are described in EP-A-0120694 and EP-A-0125023.

10 Hybridomas capable of producing antibody with desired binding characteristics are within the scope of the present invention, as are host cells, eukaryotic or prokaryotic, containing nucleic acid encoding antibodies (including antibody fragments) and capable of their expression. The invention also provides 15 methods of production of the antibodies including growing a cell capable of producing the antibody under conditions in which the antibody is produced, and preferably secreted.

The reactivities of antibodies on a sample may be determined by any appropriate means. Tagging with individual reporter molecules is one possibility. The reporter molecules may directly or indirectly generate detectable, and preferably measurable, signals. The linkage of reporter molecules may be directly or indirectly, covalently, e.g. via a peptide bond or non-covalently. Linkage via a peptide bond may be as a result of recombinant expression of a gene fusion encoding antibody and reporter molecule.

31

One favoured mode is by covalent linkage of each antibody with an individual fluorochrome, phosphor or laser dye with spectrally isolated absorption or emission characteristics. Suitable fluorochromes include fluorescein, rhodamine, phycoerythrin and Texas Red. Suitable chromogenic dyes include diaminobenzidine.

Other reporters include macromolecular colloidal particles or particulate material such as latex beads that are coloured, 10 magnetic or paramagnetic, and biologically or chemically active agents that can directly or indirectly cause detectable signals to be visually observed, electronically detected or otherwise recorded. These molecules may be enzymes which catalyse reactions that develop or change colours or cause changes in 15 electrical properties, for example. They may be molecularly excitable, such that electronic transitions between energy states result in characteristic spectral absorptions emissions. They may include chemical entities used in conjunction with biosensors. Biotin/avidin 20 biotin/streptavidin and alkaline phosphatase detection systems may be employed.

The mode of determining binding is not a feature of the present invention and those skilled in the art are able to choose a 25 suitable mode according to their preference and general knowledge.

Antibodies may also be used in purifying and/or isolating a

32

polypeptide or peptide according to the present invention, for instance following production of the polypeptide or peptide by expression from encoding nucleic acid therefor. Antibodies may be useful in a therapeutic context (which may include prophylaxis) to disrupt p21/cyclin D1/Cdk4 interaction with a view to inhibiting Cdk4 activity and so cellular proliferation. Antibodies can for instance be micro-injected into cells, e.g. at a tumour site.

10 Other candidate inhibitor compounds may be based on modelling the 3-dimensional structure of a polypeptide or peptide fragment and using rational drug design to provide potential inhibitor compounds with particular molecular shape, size and charge characteristics.

15

A compound found to have the ability to affect Cdk4 activity has therapeutic potential in anti-tumour treatment, and may be used in combination with any other anti-tumour compound. In such a case, the assay of the invention, when conducted in vivo, need not measure the degree of inhibition of binding or of modulation of Cdk4 activity caused by the compound being tested. Instead the effect on tumorigenicity and/or cell viability may be measured. It may be that such a modified assay is run in parallel with or subsequent to the main assay of the invention in order to confirm that any effect on tumorigenicity or and/or cell viability is as a result of the inhibition of binding or interaction between p21 and cyclin D1/Cdk 4 caused by said inhibitor compound and not merely a general toxic effect.

33

Following identification of a substance or agent which modulates or affects Cdk4 activity, the substance or agent may be investigated further. Furthermore, it may be manufactured and/or used in preparation, i.e. manufacture or formulation, of a composition such as a medicament, pharmaceutical composition or drug. These may be administered to individuals.

As noted, the agent may be peptidyl, e.g. a peptide which includes a sequence as recited above, or may be a functional 10 analogue of such a peptide.

As used herein, the expression "functional analogue" relates to peptide variants or organic compounds having the same functional activity as the peptide in question, which may interfere with the binding between p21 and cyclin D1/Cdk4. Examples of such analogues include chemical compounds which are modelled to resemble the three dimensional structure of the p21 or cyclin D1/Ckd4 domain in the contact area, and in particular the arrangement of the key amino acid residues identified above as they appear in human p21.

In a further aspect, the present invention provides the use of the above substances in methods of designing or screening for mimetics of the substances.

25

Accordingly, the present invention provides a method of designing mimetics of $p21^{WAF1}$ having the biological activity of Cdk4 binding or inhibition, the activity of allosteric

34

inhibition of Cdk4 and/or the activity of cyclin D1 binding, said method comprising:

- (i) analysing a substance having the biological activity to determine the amino acid residues essential and important for 5 the activity to define a pharmacophore; and,
 - (ii) modelling the pharmacophore to design and/or screen candidate mimetics having the biological activity.
- 10 Suitable modelling techniques are known in the art. This includes the design of so-called "mimetics" which involves the study of the functional interactions fluorogenic oligonucleotide the molecules and the design of compounds which contain functional groups arranged in such a manner that they could 15 reproduced those interactions.

The designing of mimetics to a known pharmaceutically active compound is a known approach to the development of pharmaceuticals based on a "lead" compound. This might be 20 desirable where the active compound is difficult or expensive to synthesise or where it is unsuitable for a particular method of administration, e.g. peptides are not well suited as active agents for oral compositions as they tend to be quickly degraded by proteases in the alimentary canal. Mimetic design, synthesis 25 and testing may be used to avoid randomly screening large number of molecules for a target property.

There are several steps commonly taken in the design of a

35

mimetic from a compound having a given target property. Firstly, the particular parts of the compound that are critical and/or important in determining the target property are determined. In the case of a peptide, this can be done by systematically varying the amino acid residues in the peptide, e.g. by substituting each residue in turn. These parts or residues constituting the active region of the compound are known as its "pharmacophore".

- 10 Once the pharmacophore has been found, its structure is modelled to according its physical properties, e.g. stereochemistry, bonding, size and/or charge, using data from a range of sources, e.g. spectroscopic techniques, X-ray diffraction data and NMR. Computational analysis, similarity mapping (which models the charge and/or volume of a pharmacophore, rather than the bonding between atoms) and other techniques can be used in this modelling process.
- In a variant of this approach, the three-dimensional structure 20 of the ligand and its binding partner are modelled. This can be especially useful where the ligand and/or binding partner change conformation on binding, allowing the model to take account of this the design of the mimetic.
- 25 A template molecule is then selected onto which chemical groups which mimic the pharmacophore can be grafted. The template molecule and the chemical groups grafted on to it can conveniently be selected so that the mimetic is easy to

36

synthesise, is likely to be pharmacologically acceptable, and does not degrade in vivo, while retaining the biological activity of the lead compound. The mimetic or mimetics found by this approach can then be screened to see whether they have the target property, or to what extent they exhibit it. Further optimisation or modification can then be carried out to arrive at one or more final mimetics for in vivo or clinical testing.

The mimetic or mimetics found by this approach can then be screened to see whether they have the target property, or to what extent they exhibit it. Further optimisation or modification can then be carried out to arrive at one or more final mimetics for *in vivo* or clinical testing.

15 Mimetics of this type together with their use in therapy form a further aspect of the invention.

The present invention further provides the use of a peptide which includes a sequence as disclosed, or a derivative, active 20 portion, analogue, variant or mimetic, thereof able to bind Cdk4 and/or inhibit Cdk4 activity, in screening for a substance able to bind Cdk4 and/or inhibit Cdk4 activity.

Generally, an inhibitor according to the present invention is provided in an isolated and/or purified form, i.e. substantially pure. This may include being in a composition where it represents at least about 90% active ingredient, more preferably at least about 95%, more preferably at least about 98%. Such

37

a composition may, however, include inert carrier materials or other pharmaceutically and physiologicaly acceptable excipients. As noted below, a composition according to the present invention may include in addition to an inhibitor compound as disclosed, one or more other molecules of therapeutic use, such as an antitumour agent.

The present invention extends in various aspects not only to a substance identified as a modulator of p21 and cyclin D1/Ckd4

10 interaction and/or Cdk4-mediated RB phosphorylation or other substrates of Cdk4 or other p21-mediated activity, property or pathway in accordance with what is disclosed herein, but also a pharmaceutical composition, medicament, drug or other composition comprising such a substance, a method comprising 15 administration of such a composition to a patient, e.g. for anti-tumour or other anti-proliferative treatment, which may include preventative treatment, use of such a substance in manufacture of a composition for administration, e.g. for anti-tumour or other anti-proliferative treatment, and a method of 20 making a pharmaceutical composition comprising admixing such a substance with a pharmaceutically acceptable excipient, vehicle or carrier, and optionally other ingredients.

A substance according to the present invention such as an 25 inhibitor of p21 and cyclin D1 and/or Cdk4 interaction or binding may be provided for use in a method of treatment of the human or animal body by therapy which affects Cdk 4 activity or other p21-mediated activity in cells, e.g. tumour cells.

38

Thus the invention further provides a method of modulating Cdk4 activity, or other p21-mediated activity in a cell, which includes administering an agent which inhibits or blocks the binding of p21 to cyclin D1 and/or Cdk4 protein, such a method being useful in treatment of cancer or other diseases or disorders including malignancies where inhibition of cellular growth and/or proliferation is desirable.

The invention further provides a method of treating tumours

10 which includes administering to a patient an agent which
interferes with the binding of p21 to cyclin D1 and/or Cdk4.

Whether it is a polypeptide, antibody, peptide, nucleic acid molecule, small molecule, mimetic or other pharmaceutically useful compound according to the present invention that is to be given to an individual, administration is preferably in a "prophylactically effective amount" or a "therapeutically effective amount" (as the case may be, although prophylaxis may be considered therapy), this being sufficient to show benefit to the individual. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, e.g. decisions on dosage etc, is within the responsibility of general practioners and other medical doctors.

25

A composition may be administered alone or in combination with other treatments, either simultaneously or sequentially dependent upon the condition to be treated.

39

Pharmaceutical compositions according to the present invention, and for use in accordance with the present invention, may include, in addition to active ingredient, a pharmaceutically acceptable excipient, carrier, buffer, stabiliser or other 5 materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere with the efficacy of the active ingredient. The precise nature of the carrier or other material will depend on the route of administration, which may be oral, or by injection, e.g. 10 cutaneous, subcutaneous or intravenous.

Pharmaceutical compositions for oral administration may be in tablet, capsule, powder or liquid form. A tablet may include a solid carrier such as gelatin or an adjuvant. Liquid pharmaceutical compositions generally include a liquid carrier such as water, petroleum, animal or vegetable oils, mineral oil or synthetic oil. Physiological saline solution, dextrose or other saccharide solution or glycols such as ethylene glycol, propylene glycol or polyethylene glycol may be included.

20

For intravenous, cutaneous or subcutaneous injection, or injection at the site of affliction, the active ingredient will be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity and 25 stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles such as Sodium Chloride Injection, Ringer's Injection, Lactated Ringer's Injection. Preservatives, stabilisers, buffers,

40

antioxidants and/or other additives may be included, as required.

Examples of techniques and protocols mentioned above can be 5 found in Remington's Pharmaceutical Sciences, 16th edition, Osol, A. (ed), 1980.

The agent may be administered in a localised manner to a tumour site or other desired site or may be delivered in a manner in 10 which it targets tumour or other cells.

Targeting therapies may be used to deliver the active agent more specifically to certain types of cell, by the use of targeting systems such as antibody or cell specific ligands. Targeting 15 may be desirable for a variety of reasons, for example if the agent is unacceptably toxic, or if it would otherwise require too high a dosage, or if it would not otherwise be able to enter the target cells.

20 Instead of administering these agents directly, they may be produced in the target cells by expression from an encoding gene introduced into the cells, eg in a viral vector (a variant of the VDEPT technique - see below). The vector may targeted to the specific cells to be treated, or it may contain regulatory elements which are switched on more or less selectively by the target cells.

The agent may be administered in a precursor form, for

41

conversion to the active form by an activating agent produced in, or targeted to, the cells to be treated. This type of approach is sometimes known as ADEPT or VDEPT, the former involving targeting the activating agent to the cells by conjugation to a cell-specific antibody, while the latter involves producing the activating agent, e.g. an enzyme, in a vector by expression from encoding DNA in a viral vector (see for example, EP-A-415731 and WO 90/07936).

10 A composition may be administered alone or in combination with other treatments, either simultaneously or sequentially dependent upon the condition to be treated, such as cancer, virus infection or any other condition in which a p21-mediated effect is desirable.

15

Nucleic acid according to the present invention, encoding a polypeptide or peptide able to interfere with p21 and cyclin D1 and/or Cdk 4 interaction or binding and/or induce or modulate Cdk4 activity or other p21-mediated cellular pathway or 20 function, may be used in methods of gene therapy, for instance in treatment of individuals with the aim of preventing or curing (wholly or partially) a tumour e.g. in cancer, or other disorder involving loss of proper regulation of the cell-cycle and/or cell growth, or other disorder in which specific cell death is 25 desirable, such as in certain viral infections.

Vectors such as viral vectors have been used in the prior art to introduce nucleic acid into a wide variety of different

42

target cells. Typically the vectors are exposed to the target cells so that transfection can take place in a sufficient proportion of the cells to provide a useful therapeutic or prophylactic effect from the expression of the desired polypeptide. The transfected nucleic acid may be permanently incorporated into the genome of each of the targeted tumour cells, providing long lasting effect, or alternatively the treatment may have to be repeated periodically.

10 A variety of vectors, both viral vectors and plasmid vectors, are known in the art, see US Patent No. 5,252,479 and WO 93/07282. In particular, a number of viruses have been used as gene transfer vectors, including papovaviruses, such as SV40, vaccinia virus, herpesviruses, including HSV and EBV, and 15 retroviruses. Many gene therapy protocols in the prior art have used disabled murine retroviruses.

As an alternative to the use of viral vectors other known methods of introducing nucleic acid into cells includes 20 electroporation, calcium phosphate co-precipitation, mechanical techniques such as microinjection, transfer mediated by liposomes and direct DNA uptake and receptor-mediated DNA transfer.

25 Receptor-mediated gene transfer, in which the nucleic acid is linked to a protein ligand via polylysine, with the ligand being specific for a receptor present on the surface of the target cells, is an example of a technique for specifically targeting

43

nucleic acid to particular cells.

A polypeptide, peptide or other substance able to interfere with the interaction of the relevant polypeptide, peptide or other substance as disclosed herein, or a nucleic acid molecule encoding a peptidyl such molecule, may be provided in a kit, e.g. sealed in a suitable container which protects its contents from the external environment. Such a kit may include instructions for use.

10

Various further aspects and embodiments of the present invention will be apparent to those skilled in the art in view of the present disclosure. Certain aspects and embodiments of the invention will now be illustrated by way of example and with 15 reference to the following figures:

Figure 1. The Ability of Peptides from p21WAF1 to Interact with Cdk4 and Cyclin D1.

Figure 1a: a list of the peptides 1-11 based on the sequence of peptides were bound to 20 p21 WAF1. Figure 1b: The WAF21 streptavidin-agarose beads and added to reticulocyte lysates either Cdk4 or cyclin Dl labelled with containing [35S] methionine. After extensive washing bound proteins were analysed using SDS-PAGE followed by autoradiography. The bands 25 were quantified using a Bio-Imager and Whole Band Analysis Software (Millipore). The results are representative of 3 such experiments. "x" indicates beads without peptide.

Figure 2. Addition of p21^{WAF1} Based Peptides to Cyclin D1-Cdk4 Phosphorylation Assays.

Cyclin D1-Cdk4 assays were carried out in vitro using lysates from Sf9 insect cell following co-infection with Cdk4 and cyclin D1 baculovirus constructs and GST-Rb as the substrate. p21WAF1 peptides were added to the assays at a concentration of 17 μM and the effect on Cdk4 activity was assessed by SDS-PAGE and autoradiography. The figure shows quantification of the autoradiograph using bio-imaging, relative binding is expressed in terms of Cdk4 activity in the absence of peptide. The data are representative of 4 experiments. "x" indicates no addition of peptide.

Figure 3. Quantification of Peptide Inhibition.

15 Peptides 4, 8, 2 and 10 were added to cyclin D1-Cdk4 assays at various concentrations between 0.01-34 μM . The figure gives a plot of activity (%) relative to Cdk4 activity measured in the absence of peptide against peptide concentration and the $I_{0.5}$ for each peptide. The data represent the mean of 3 experiments.

20

Figure 4. Peptides 2 or 10 are Not Substrates for Cyclin D1-Cdk4.

The figure shows the results of phosphorylation assays using peptides 2, 4 & 10.

25

Figure 5. Size Scan of Peptide 10.

The figure shows the sequences of a series of peptides based on peptide 10 designed to find the minimal inhibitory domain. The

45

boxed residues represent the minimal inhibitory domain. The peptides ware added to cyclin D1-Cdk4 assays and analysed by SDS-PAGE and autoradiography.

5 Figure 6. Alanine Scan Mutations of Peptide 10.

In order to pinpoint residues that were critical for the inhibition of Cdk4 by peptide 10 a series of point mutations were constructed in which each residue was sequentially changed to alanine. The peptides were added to cyclin D1-Cdk4 assays and the results were analysed by SDS-PAGE and autoradiography then quantified using a Bio-Imager. The results are expressed relative to Cdk4 activity in the absence of peptide and are representative of 3 experiments. Having identified the critical residues we then synthesised an untagged eight amino acid peptide which contained the R, L and F (KRRLIFS) and determined the phosphorylation of GST-Rb by cyclin D1-Cdk4 in the presence of increasing concentrations of this truncated peptide.

Figure 7. Comparison of Inhibitory Peptides with Full Length 20 p21WAF1 Protein.

This shows concentration curves for peptide 10, D to A mutant peptide 10, a p16INK4 derived peptide (Fahraeus et al., 1996) and full length his-p21 WAF1 determined using the cyclin D1-Cdk4 assay analysed by SDS-PAGE, autoradiography and bio-imaging and 25 for the $I_{0.5}$ of each inhibitor. The results are the mean of 3 such experiments.

46

Figure 8. Binding and Inhibitory Domains of p21WAF1.

The hatched residues show the regions of p21WAF1 identified in this study as being important for cyclin D1 and Cdk4 binding, and Cdk4 inhibition in the N-terminal domain, as well as a novel inhibitory domain in the C-terminus of p21WAF1. The residues found to be important for the interaction of p21WAF1 with PCNA (Warbrick et al., 1995) are shown in black. In addition, the smallest portion of p21WAF1 that was found to inhibit CDK activity in vitro (Luo et al., 1995) prior to the present study 10 is indicated.

Figure 9. Introduction of p21WAF1 based peptides into cells A series of synthetic peptides based on the sequence of peptide 10 (Peptides I, II and III, shown in Figure 9a) were synthesised 15 with carrier peptide (shaded sequences). The underlined residue in peptide-I is the M to A mutation which prevents PCNA binding. The peptides were added to proliferating HaCaT cells, grown in DMEM plus 10% FCS. The cells were incubated for 24 hours pulse labelled during with 15 μM BrdU, fixed and then analysed by 20 FACS. The G_1 -, S- and G-phase distributions for untreated cells, Peptide-I at $25\mu M$, Peptide-II at $50 \mu M$ and Peptide-III at 25 μ M, were determined. Figure 9b shows the data represented as the % of cells in each phase compared to the total number of cells counted. The results of similar experiments using MCF7 25 and MRC5 cells are shown in Figure 9c, which shows the percentage of cells in each phase of the cell cycle in the absence and presence of peptide I.

47

In a separate experiment DMEM + 10% FCS alone or DMEM + 10% FCS containing either 25 µM Peptide-I or 50µM Peptide-II, was added to HaCaT cells than had been starved for 72 hours. Samples were taken at the times shown and analysed by SDS-PAGE/Western blot stained for pRb. pRb represents hypophosphorylated Rb protein and pRb* refers to hyperphosphorylated Rb protein. It should be pointed out that equal amounts of total protein were loaded per lane and that the antibody appears to preferentially recognise phosphorylated forms of the Rb protein.

10

Figure 10. Inhibition of cyclin-Cdk4 activity using derivatives of peptide 2.

The figure shows the degree of inhibition of cyclin D1-Cdk4 activity using pRb as a substrate, by peptide 2 (2 on the 15 figure) and alanine scan mutations of the peptide (each residue being sequentially mutated to alanine). Activity is given relative to uninhibited activity. (No is short for no added peptide.) Peptides were present at a concentration of 10 μ M. A similar pattern is seen when binding of peptide 2 mutants to 20 cyclin D1 expressed in reticulocyte lysates.

Important residues for the binding and inhibition are the two arginine residues (R) and the phenylalanine (F) with the lysine (K) and proline (P) also contributing. This is different from 25 residues identified as being critical for interaction of full length protein with cyclin D1, as these studies pick out the LFG motif as being most important for activity.

48

Experimental Procedures

Peptides

All peptides were synthesised by Chiron Mimotopes, Peptide 5 Systems (Clayton, Australia). Each peptide had a Biotin-SGSG spacer at the C-terminus and a free N-terminus. The peptides were dissolved in DMSO at approximately 5 mg/ml and we then determined their concentration precisely by amino acid analysis (Smythe et al., 1988). In addition the purity of the peptides 10 was estimated using mass spectrometry. Positive electrospray mass spectrometry was performed triple-quadruple mass spectrometer (V. G. Quattro) in (50/50/0.1) water/acetonitrile/formic acid.

15 Proteins

Cyclins and CDKs - Cdk4 and cyclin D1, Cdk2 and cyclin E and Cdc2 and cyclin B were co-expressed in Sf9 insect cells infected with the appropriate baculovirus constructs. The cells were harvested two days after infection by low speed centrifugation 20 and the pellet was lysed in an equal volume of 10 mM Hepes, pH 7.4 containing: 10 mM NaCl, 1 mM EDTA, and 0.1 mM phenylmethane sulphonyl fluoride, 2 mM DTT and centrifuged at 14000 x g for 15 min. The supernatant was removed, aliquoted and immediately frozen in liquid nitrogen. Thawed lysate was used only once and 25 was never refrozen. Labelled Cdk4 and cyclin D1 were produced by translation in the presence of [35S] methionine using a rabbit reticulocyte lysate in vitro translation kit (Promega).

49

His-tagged p21WAF1 - Human p21WAF1 was expressed in E.coli using a PET expression vector. The soluble p21WAF1 protein fraction was purified using a nickel chelating column, following the manufacturers instructions (Pharmacia). The eluted protein peak was dialysed against 25 mM Hepes, pH 7.4, containing: 0.1 mM EDTA, 1 mM benzamidine, 0.01% Triton X-100, and 0.1 mM phenylmethane sulphonyl fluoride, concentrated and applied to a Superose 12 gel-filtration column (Phamacia) equilibrated in the above buffer. Fractions containing p21WAF1 were detected by Western blot using the p21WAF1 specific monoclonal antibody Ab-1 (Oncogene Sciences), concentrated to 200 μg/ml and stored at -70°C.

GST-Rb - An E. coli expression construct containing the
15 hyperphosphorylation domain of pRb (amino acids 773-924) was
purified on a glutathione-Sepharose column according to the
manufacturers instructions (Pharmacia).

Peptide Precipitation of Cdk4 and Cyclin Dl

20 A 20 amino acid peptide library, that spanned the entire sequence of p21^{WAF1} (Figure 1), was screened for Cdk4/cyclin D1 interacting peptides. Peptide (1.5 μ g) was diluted in 100 μ l of PBS and incubated with 10 μ l of packed streptavidin-agarose beads (Sigma) for 1 h at room temperature. Unbound peptide was 25 removed by extensive washing with PBS and the beads, plus bound peptide, were incubated for 1h at 4°C with reticulocyte lysate containing either Cdk4 or cyclin D1 labelled with [35 S] methionine. The beads were washed three times with 1.25 x PBS

50

containing 0.2% Triton X-100 and boiled in the presence of 0.125 M Tris-HCl, pH 6.8 containing: 4% (w/v) SDS, 20% (v/v) glycerol and 200 mM DTT. The bound protein was analysed by SDS-PAGE followed by auto-radiography and quantification of the 5 35S-labelled protein using a Bio-Imager and Whole Band Analysis Software (Millipore).

Enzyme Assays

Phosphorylation of GST-Rb - Cdk4 activity was measured using the cyclin D1-Cdk4 containing insect cell lysate described above. Extract (1 μl) was added to a final reaction volume of 10 μl, containing: 50 mM Hepes, pH 7.4, 10 mM MgCl2, 2.5 mM EGTA, 1 mM DTT, 10 mM β-glycerophosphate, 1 mM NaF, 10 mM PKI, 50 μM ATP containing [³²P] ATP (1 000 cpm/pMol) and 0.5 μg GST-Rb. The 15 assays were started by the addition of the GST-Rb substrate, incubated at 30°C for 10 min (the incorporation of P into GST-Rb was linear over 15-20 min) and terminated by adding SDS-PAGE sample buffer and heating at 95°C for 4 min. The samples were analysed by SDS-PAGE on 12% gels followed by 20 auto-radiography and quantification using a Bio-Imager.

Peptide phosphorylation

The biotinylated peptides (1 μ g) were incubated for 30 min at 30 °C in a final volume of 20 μ l containing: 50 mM Hepes, pH 25 7.4, 10 mM MgCl₂, 2.5 mM EGTA, 1 mM DTT, 10 mM β -glycerophosphate, 1 mM NaF, 10 mM PKI, 50 μ M ATP containing [32 P]ATP (6000 cpm/pMol) and either 1 μ l of cyclin D1-Cdk4 insect cell lysate, 1 μ l of uninfected insect cell lysate or

51

0.02 mU of protein kinase C plus 0.5 mM CaCl₂, 100 mg/ml phosphatidyl serine and 20 mg/ml diacylglycerol. The reactions were stopped by heating at 60°C for 5 min and streptavidin agarose beads were added (10µl packed cell volume washed with 5 3 x PBS) and incubated with shaking at 4oC for 30 min. The beads were washed extensively with PBS containing 3% (v/v) Tween-20 and the incorporation of radioactivity into the peptides was determined by Cerenkov counting.

10 Cell Cycle Measurements

Carrier linked peptides were designed for delivery into proliferating HaCaT cells (see Figure 9). Cells were seeded on 30mm culture plates and grown to 50% confluency in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% (v/v) 15 foetal calf serum (FCS). Peptides were added to the medium and the cells were incubated for 24 hours. During the last 30 minutes of the incubation the cells were pulse labelled in the presence of 15µM BrdU. The cells were trypsinised, fixed in absolute alcohol and prepared for FACS analysis using a single 20 laser flow cytometer (Becton-Dickinson, FACScan) as previously described (Renzing et al, 1996).

pRb Phosphorylation in HaCaT Cells

HaCaT cells were seeded on 30mm culture plates at 25% confluency
25 in DMEM with 10% FCS. The FCS was withdrawn after 24 hours and
the cells were starved for 72 hours. At the end of this period
the medium was supplemented with 10% FCS and carrier linked
peptides. Samples were taken over a 24 hour time course and the

52

cells were lysed in RIPA buffer (50 mM Tris-HC1, pH 8.0, containing 150 mM NaC1, 1.0% (v/v) NP-40, 0.5% (w/v) DOC, 0.1% (w/v) SDS,1 mM PMSF, 0.1 mg/ml aprotinin and 0.5 mg/ml leupeptin) for 30 minutes at 4°C. The phosphorylation statues of pRb was determined by Western blot analysis, as previously described (Fåhraeus et al, 1996) except that the blot was probed with a pRb polyclonal antibody (C-15, Santa Cruz).

Results

Peptide-Binding Assay for Cyclin D1 and Cdk4

Using a series of synthetic peptides that span the entire sequence of p21^{WAF1} (Figure 1), we determined whether these peptides could mimic full length p21^{WAF1} protein by forming a 15 stable complex with either cyclin D1 or Cdk4. If peptide-binding mimetics of p21^{WAF1} protein could be identified, then this would assist in identifying the minimal binding motif of p21^{WAF1} protein required for cyclin D1-Cdk4 holoenzyme inhibition and whether p21^{WAF1} was targeting the cyclin or the 20 kinase subunit. This would also define a system for using small peptides to study p21^{WAF1} protein reaction mechanism and to design mimetic drugs.

The peptide-binding assay involved quantifying the amount of 25 ³⁵S-labelled cyclin D1 or Cdk4 which bound specifically to biotinylated peptides that were captured on streptavidin coated agarose beads. The peptide-coated beads were added to extracts containing either ³⁵S-labelled cyclin D1 or Cdk4 translated in

vitro, the beads were washed extensively to remove unbound protein, and the bound cyclin D1 or Cdk4 was quantified by SDS-PAGE followed by auto-radiography and bio-imaging. This is referred to below as a peptide precipitation assay and has been used previously to demonstrate evolutionary conservation of p21WAF1 binding to PCNA (Ball and Lane, 1996).

A Small Peptide Derived from Amino Acids 46-65 in the N-Terminal Domain of p21^{WAF1} Binds Directly to Cdk4

10 Using the peptide-precipitation assay, peptide 4 (from the N-terminal domain of $p21^{WAF1}$) bound specifically to Cdk4, but not to cyclin D1 (Figure 1). This interaction is physiologically important, since the CDK interacting domain of the p21WAF1 protein has previously been proposed to localise to 15 the N-terminal domain of the molecule (Chen et al., 1995; Harper et al., 1995; Luo et al., 1995). More specifically, deletions (Nakanishi et al., 1995a) or mutations (Goubin and Ducommun, 1995) in the region of amino acids 45-71 compromise the ability of full length p21WAF1 to interact with Cdk2. Whether this loss 20 of p21WAF1 binding function is due to, (i) mutation/deletion of residues directly involved in CDK binding, or (ii) mutations/deletion induced conformational alterations in p21WAF1 that prevent stable binding to CDK, has not been demonstrated. Here we show unequivocally that residues 46-65 25 are directly involved in the binding of p21WAF1 to Cdk4 and that alone they are capable of forming a stable complex with Cdk4, in the absence of cyclin D1. Thus, providing direct evidence that the N-terminus of p21 WAF1 does contain a kinase binding

domain.

A Small Peptide Derived from Amino Acids 16-35 in the N-Terminus of p21WAF1 Binds Directly to Cyclin D1

- 5 We were also able to define a second and distinct N-terminal interaction site on the p21WAF1 protein; in this case a region of p21WAF1 which is capable of binding to cyclin D1, but not to Cdk4 (Figure 1). Peptide 2 comprises amino acids 16-35 of p21WAF1 and lies within the Eminimum region required for DNA 10 synthesis inhibition in vivo, which is located between residues 17-71 (Nakanishi et al., 1995a). Our results might explain an apparent contradiction encountered by Nakanishi et al. (1995a) who found that N-terminal mutations in p21WAF1 protein which are outside the CDK interacting domain, although insufficient to 15 prevent binding to the kinase, were sufficient to prevent p21WAF1 from acting as a growth suppressor when transfected into proliferating cells. Specifically, the direct peptide binding data (Figure 1) leads us to suggest that an N-terminal motif in the p21WAF1 protein, that mediates cyclin D1 binding, could be 20 an essential step in the mechanism through which p21WAF1 protein functions as a growth suppressor.
 - A Novel Cyclin D1-Cdk4 Binding Motif Resides in the C-Terminus of the $p21^{WAF1}$ Protein
- The specificity of the peptide-precipitation assay in defining the domain of p21^{WAF1} protein required for binding to either the cyclin D1 or Cdk4 (Figure 1), indicated that using peptides to study potential interactions between p21^{WAF1} and cyclin-CDK

WO 97/42222

complexes would prove to be very informative. We were intrigued however, by the finding that peptides from the C-terminus of the p21WAF1 protein (peptides 10 and 11) could form stable complexes with both Cdk4 and cyclin D1 (Figure 1), as peptide 10 is 5 equivalent to the p21PBP peptide described by Warbrick et al. (1995) as representing the region of $p21^{WAF1}$ which binds to the replication/repair protein PCNA. We can not rule out the possibility that endogenous cyclin or CDK present reticulocyte lysate could bind to the labelled human protein 10 forming a bridge to the peptide. However, as peptide 2 and peptide 4 precipitate either cyclin D1 or Cdk4, respectively, this seems unlikely. These results suggest that the p21WAF1 protein may interact with both PCNA and cyclin-CDK complexes through the same binding motif. Peptide 11 however, binds to 15 both Cdk4 and cyclin D1 but not to PCNA (Figure 1) (Warbrick et al., 1995; Ball and Lane, 1996); uncoupling the PCNA binding site from the cyclin/CDK binding motif in the C-terminus of p21WAF1

- 20 Given that we had identified three distinct motifs from the p21^{WAF1} protein which bind specifically to cyclin D1 and/or Cdk4, we then examined whether they mimicked p21^{WAF1} protein by inhibiting kinase activity.
- 25 The Cyclin D1 Binding Peptide from the N-Terminal Domain of p21 WAF1 and the Cyclin/CDK Binding Peptide from the C-Terminus of p21 WAF1 Inhibits the Activity of Cdk4

In order to determine if any of the p21 WAF1 peptides possessed

56

Cdk4 inhibitory activity we tested, independently, their ability to prevent pRb phosphorylation during cyclin D1-Cdk4 assays in vitro (Figure 2). Peptides 2, 8,10, and 11 inhibited cyclin D1-Cdk4 activity when added to the assay at 17 µM, whereas 5 buffer alone and the remaining peptides had no dramatic affect on Cdk4 activity. The cyclin D1 binding peptide (peptide 2) inhibited the kinase activity by approximately 80% and peptides 10 and 11, which bound both Cdk4 and cyclin D1, completely inhibited enzyme activity at this concentration. Thus, there 10 is a correlation between the ability of the peptides to bind to Cdk4 and/or cyclin D1 and to inhibit Cdk 4 kinase activity.

However, this correlation breaks down in the case of kinase-binding peptide 4. This peptide maps to the CDK 15 interaction site (Figure 8; Goubin and Ducommun, 1995; Nakanishi et al., 1995a) and there has been speculation that a peptide from this domain, capable of interacting with CDK, would mimic full-length $p21^{WAF1}$ inhibitory activity, and would therefore provide a model for the design of novel molecules that could 20 arrest cell cycle progression by inhibiting the G1 cyclin-CDKs. Although of high affinity for Cdk4, peptide 4 had no inhibitory activity when added to cyclin D1-Cdk4 assays at concentrations of up to 35 μM . Our data from both p21 WAF1 -peptide binding data and inhibitory properties, therefore pinpoints two novel small 25 domains of the p21 WAF1 protein as potential candidates for small molecular weight mimetics; an N-terminal motif from amino acids 16-35 (peptide 2) and a C-terminal motif from amino acids 141-160 (peptide 10).

57

It is thus possible that peptide 4 could block p21 binding, preventing its activity as an inhibitor. Thus cells treated with peptide 4 may be expected to continue to proliferate even in the presence of competing signals which would normally 5 mediate cell cycle arrest or apoptosis. Thus peptide 4 may be used to reversibly immortalise cells, by supplying to the peptide to the cells. This provides a further tool in investigating the cellular mechanisms for control of the cell cycle and may also be useful in combatting cell loss in conditions associated with loss of cells, such as in AIDS or degenerative conditions including MS, dementia, or in muscle degenerative conditions such as muscular dystropy (MD) including Duchenne MD.

15 The C-Terminal p21WAF1 Peptide is a More Potent Inhibitor of Cdk4 Kinase Activity than the N-Terminal Cyclin D1-Binding Peptide

We carried out more detailed studies to determine the $I_{0.5}$ for peptides 2, 8, and 10, using peptide 4 as a negative control 20 (Figure 3). We found that peptide 10 (and peptide 11; data not shown) was a potent inhibitor of Cdk4 activity with an $I_{0.5}$ of 0.1 μ M, peptide 2, was also a good inhibitor with an $I_{0.5}$ of 2 μ M. Peptide 8 gave only weak inhibition and relatively high concentrations of peptide were required to approach 50% 25 inhibition. These data support the possibility of using peptide 2 or peptide 10 to mimic the CDK inhibitory activity of the full length p21 WAF1 protein.

58

p21WAF1 Protein and Inhibitory Peptides Compete for the Same Binding Site on Cdk4 Kinase

In order to determine if the Cdk4 inhibitory peptides, 2 and 10, were acting at sites on Cdk4 and cyclin D1 that were also 5 employed by p21^{WAF1}, we carried out peptide precipitation assays in the presence and absence of full length purified his-p21^{WAF1} to find out if it competed with the peptides for binding.

- 10 The ability of p21^{WAF1} to interfere with peptide 2 (A) and peptide 10 (B & C) binding to Cdk4 and/or cyclin D1 was determined by carrying out the peptide precipitation assay from reticulocyte lysates in the presence of 0, 0.5, 2 μg of p21^{WAF1}.
- 15 The data suggest that binding of p21WAF1 protein to cyclin D1 and Cdk4 prevents binding of both peptide 2 and peptide 10. These data are open to two interpretations, (i) the peptides could be competing for binding at the same site as p21WAF1, or (ii) binding of either p21WAF1 or peptide could cause a 20 conformational change in the cyclin or CDK preventing further binding. It is not clear from these experiments whether peptides 2 and 10 are acting at the same site(s). However the difference
- of the sites is unique, as peptide 10 can precipitate both Cdk4 25 and cyclin D1, whereas, peptide 2 can only precipitate cyclin D1.

in the peptide precipitation data, indicates that at least one

Data to support the hypothesis that peptide 10 and p21WAF1

59

protein compete for the same binding site, during kinase inhibition, employs the use of a peptide 10 mutant (containing a point mutation resulting in a change of R - A at residue 15 of peptide 10 which is equivalent to residue 155 of the full length protein) which loses >60% of its inhibitory activity (see below), but retains its binding function.

To determine if the inhibition of Cdk4 by p21WAF1 could be relieved by the addition of a peptide 10 mutant, the R to A 10 mutant (residue 15 of peptide 10) that was no longer an efficient inhibitor but still displayed partial binding activity, increasing concentrations of peptide (1, 5, 17 & 34 μM) were added to cyclin D1-Cdk4 GST-Rb phosphorylation assay in the presence of a fixed concentration of p21WAF1 (50 μM).

15

The experiment showed that increasing concentrations of mutant peptide 10 were able to block the inhibitory activity of full length p21^{WAF1} suggesting that peptide 10 is binding at a site(s) which blocks subsequent binding of p21^{WAF1} and is therefore functioning through a similar mechanism to the full length protein.

The Inhibitory Peptides are not Cyclin D1-Cdk4 Substrates
Unlike the p107 protein, which appears to inhibit Cdk4s ability
25 to phosphorylate pRb by acting as an alternative substrate (Zhu et al., 1995), p21WAF1 has not been reported to act as a substrate for the cyclin D1-Cdk4 complexes (and we confirm these observations Figure 4). However, it is possible that by using

60

p21WAF1 based peptides, instead of full length protein, we have inadvertently generated phosphorylation sites which would not normally be exposed on the surface of the protein. peptides could be acting as competitive substrates as opposed 5 to inhibitors of catalytic activity. Both peptide 2 and peptide 10 contain a number of possible phosphorylation sites, and we have been able to demonstrate that peptide 10 is a potential substrate for a number of protein kinases (data not shown), including protein kinase C (PKC) which was used as a control 10 kinase (Figure 4). In fact, neither peptide 2 nor peptide 10 were substrates for cyclin D1-Cdk4 under conditions where 2.4 nMol of ³²P were incorporated per nMol of GST-Rb. However, under the same conditions peptide 10 was an extremely good substrate for PKC with 0.82 nMol of 32P being incorporated per nMol of 15 peptide (Figure 4). There was a low level of incorporation into peptide 2, but as this was also present in assays using lysate from uninfected insect cells it must be attributed to low levels of endogenous protein kinase(s). Thus, it appears that the peptide inhibitors are not competitive substrates, but, are 20 acting to block catalytic activity in a mechanism similar to p21WAF1.

The Peptides are not Efficient Inhibitors of Cyclin B-Cdc2 Kinase Activity

25 Harper et al. (1995) have shown that p21^{WAF1} is not a universal CDK inhibitor, but that it displays selectivity for the G1 and S-phase cyclin-CDK complexes. When they compared the ability of p21^{WAF1} to inhibit Cyclin B-Cdc2, which acts at the G2/M

61

transition, and cyclin D2-Cdk4, which functions during G1, they found that the I_{0.5} for inhibition of cyclin B-Cdc2 was > 600-fold higher than the I_{0.5} for inhibition of cyclin D2-Cdk4 using purified recombinant proteins. We looked at the effect of adding our two cyclin D1-Cdk4 inhibitory peptides to cyclin B-Cdc2 and Cdk2-cyclin E assays at concentrations up to 20 µM and found that neither peptide 2 nor peptide 10 had a significant effect on Cdc2-cyclin B histone H1 kinase activity. However, Cdk2-cyclin E was inhibited by peptide 10, showing that peptide 10 can inhibit other G₁ cyclin-Cdk complexes. Thus, the p21WAF1 based peptide inhibitors appear to have equivalent specificity to the full length protein.

To determine if peptides 2 and 10 could inhibit cyclin B-Cdc2 and cyclin E-Cdk2 kinase activity assays were performed using Sf9 cell lysates which were co-expressing human cyclin B and Cdc2. The conditions were identical to those described in the Experimental Procedures for cyclin D1-Cdk4 except that histone H1 (0.5 μ g/assay) was used as the substrate for cyclin B-Cdc2.

20 Cyclin D1-Cdk4 cyclin B-Cdc2 and cyclin E-Cdk2 were assayed in the presence of increasing concentrations of peptide 2 (0.25, 3, 10 and 40 μ M) and peptide 10 (0.1, 0.5, 5, 20 μ M).

The Kinase Inhibitory Motif of Peptide 10 is Distinct from the 25 PCNA Binding Site

We have shown that peptide 10 is an extremely potent inhibitor of cyclin D1-Cdk4 activity, with an $I_{0.5}$ of 0.1 mM which is 20-fold more potent than peptide 2, a peptide derived from the

region of p21WAF1 previously associated with growth arrest (Chen et al.,1995; Nakanishi et al., 1995a). We have also shown that a peptide (peptide 4) which spans the CDK interaction site of p21 WAF1 (Goubin and Ducommun, 1995; Nakanishi et al., 1995a), 5 although capable of binding to Cdk4 to form a stable complex, has no detectable activity as a cyclin D1-Cdk4 inhibitor. Peptide 10 therefore looks like the best candidate for the development of a small peptide mimetic with high efficacy. Peptide 10 has previously been shown to form a 10 high-affinity and reversible interaction with PCNA (Ball and Lane, 1996) and this peptide is sufficient to partially inhibit the function of PCNA during SV40 replication giving 50% inhibition at a concentration of approximately 7 mM (Warbrick et al., 1995). The PCNA interaction domain of p21WAF1 has been 15 mapped and the important residues were found to be amino acids 144-151 (QTSMTDFY; Warbrick et al., 1995; Ball and Lane, 1996). Although the extreme C-terminal peptide (peptide 11) has amino acid residues important for binding to and inhibiting Cdk4 (see Figure 1 and 2), it cannot bind PCNA (Warbrick et al., 1995; 20 Ball and Lane, 1996). These results indicate that the kinase inhibitory and PCNA binding motif in the C-terminus of p21WAF1 are distinct, but it does not rule out the possibility that an interaction between p21WAF1 and PCNA or cyclin/kinase may require some common amino acids. It is therefore important to 25 identify the precise inhibitory motif within the C-terminus of p21 WAF1 and establish if it overlaps, or is distinct from, the PCNA interaction domain. To investigate this question we took two approaches; we synthesised, (i) a series of peptides that

63

had been shifted by 4 amino acids in either direction along peptide 10 (size scan; Figure 7), and (ii) a series of peptides based on peptide 10 where each residue was sequentially mutated to alanine (alanine scan; Figure 6). The ability of the 5 peptides, in each of these two series, to inhibit Cdk4 activity in vitro was then determined. Using the size scan, we found that the peptide inhibition activity required amino acids 156-160, while amino acids 148-155 were dispensable. This uncouples the kinase inhibitory motif from the PCNA binding 10 motif.

With the alanine scan we defined the critical residues for inhibition showing that a stretch of just 5 amino acids were essential for activity, with a single conservative point 15 mutation at either of two hydrophobic residues completely abolishing peptide 10 inhibitory activity (Figure 6). The essential amino acids are RRLIF (amino acids 155-160) where the bold characters are essential for activity and the underlined residue contributes significantly to inhibitory activity.

20

When tested in the peptide precipitation assay, mutation of the first R of this motif to A (aa 155 of full length p21WAF1) partially retained its ability to bind both Cdk4 and cyclin D1, whereas mutations of L or F to A significantly decreased the 25 affinity for Cdk4 and cyclin D1, and mutations of the second R or the I had no effect on binding (data not shown). This is why the R - A mutant was used in competition assays. The fact that a single point mutation in either of two hydrophobic residues

64

(the L or F residues) completely abolishes inhibitory activity, suggested that inhibition was due to a specific interaction at key hydrophobic residues. The mapping data also explains why both peptide 10 and peptide 11 are good inhibitors of cyclin 5 D1-Cdk4 activity (Figure 2) as they both contain the inhibitory motif. Thus, it appears that the inhibitory portion of peptide 10 does not overlap with the PCNA binding site as they have no amino acid residues in common.

- 10 A Single Amino Acid Substitution in Peptide 10 Makes it a More
 Potent Inhibitor thus Approaching the Specific Activity of Full
 Length p21WAF1 Protein
 - Whilst carrying out the alanine scan experiments we noticed that one of the mutant peptides (D A at position 9 of peptide 10
- 15 or 149 of the full length protein; Figure 6) appeared to make the peptide a better inhibitor of cyclin D1-Cdk4 activity. We determined the $I_{0.5}$ for this peptide and compared it with peptide 10, full length purified his-p21 MAF1, and a peptide derived from the tumour suppressor protein p16 INK4 which has
- 20 recently been reported to inhibit cyclin D1-Cdk4 activity in vitro and to prevent cell cycle progression (Fahraeus et al, 1996). The D-A
 - mutation decreases the $I_{0.5}$ from 100 nM to 46 nM (Figure 7). Comparing this with the pl6INK4-based peptide, which has an $I_{0.5}$
- 25 of 16.3 μ M (Figure 7), we have now produced a peptide which is approximately 350-fold more active as a Cdk4 inhibitory compound. In fact, we now begin to approach the potency of p21^{WAF1} itself, which has an I_{0.5} of 11 nM in the insect cell

65

lysate assay (Figure 7). This value is in the same range as the Ki of 40 nM for p21WAF1 obtained for the inhibition of cyclin D1-Cdk4 in Sf9 cell lysates by Harper et al. (1995). Compared to full length protein, the mutant peptide 10 has only a 3.5-fold lower specific activity as a kinase inhibitor in crude lysates. Why mutating the D - A in this position, which is well out side the domain shown to be essential for activity, reduces the I_{0.5} is not known. It seems likely that it involves the presentation of the inhibitory motif, rather than a direct 10 role for this residue in inhibition, as this mutation does not appear to increase the affinity of the peptide for either Cdk4 or cyclin D1 (data not shown).

The results indicate that peptide 10 could be used as a model on which to base small peptide mimetics of p21^{WAF1} and we have provided evidence that alterations in the peptides structure or presentation of the active residues may lead to the generation of a peptide inhibitor which approaches the potency of full length p21^{WAF1} as a cyclin D-Cdk4 inhibitor.

20

Results for the C-terminal peptide (peptide 10)

An Eight Amino Acid Peptide is Sufficient to Inhibit Cyclin D-Cdk4 Activity

Having identified residues which appeared to be critical for the inhibition of cyclin D1-Cdk4 by peptide 10, we determined if these residues were sufficient for inhibition, or if they had to be presented within the context of a larger peptide. Strikingly, the eight amino acid peptide, KRRLIFSK, retained the

66

ability to completely inhibit cyclin D1-Cdk4 activity and prevent phosphorylation of pRb (Figure 6). However, the $I_{0.5}$ for the truncated peptide was approximately 1000-fold higher than that of the full length peptide ($I_{0.5}$ for the truncated 5 peptide was approximately 100 μ M). This was not an unexpected result as other studies have shown loss of potency upon reducing the length of bio-active peptides. However, it may be possible to improve the peptide inhibitory activity by manipulating the non-essential residues in a manner defined by Lin et al (1995) 10 in an elegant series of experiments aimed at minimising the atrial natriuretic peptide.

Peptide 10 works in cell systems

The introduction of p21WAF1 cDNA into human brain, lung and colon cancer cell lines leads to a suppression of cell growth (El-Deiry et al, 1993). In addition, during a radiation-induced G1 arrest in human fibroblasts p21WAF1 protein levels increase, in a p53-dependent manner, leading to potent inhibition of the G1 cyclin-CDKs and failure of the cells to enter S-phase (Dulic et al, 1994; Harper et al, 1995). In order for peptide 10 to function as a realistic template for the design of novel antiproliferative drugs it must be able to mimic p21WAF1's CKI activity as a growth suppressor in a cellular background. We and others have recently shown that a 16 amino acid sequence from the homeodomain of the Antennapedia protein can act as a carrier for peptides with biological activity, translocating them across the plasma membrane and allowing them to interact with their target molecules (Fåhraeus et al, 1996; Hall et al,

67.

1996). To determine if peptide 10 retained its biological activity when introduced into tissue culture cells, we synthesised it directly onto the carrier peptide and added it to a culture of proliferating asynchronous human kerotinocyte-derived HaCaT cells. The linked peptide (designated Peptide-I; Figure 9) contained a mutation of M to A at position 7, thus abolishing its activity as a PCNA binding peptide (Warbrick et al, 1995; Ball and Lane, 1996), and allowed us to study PCNA-independent affects of the peptide on normal cell cycle.

10

Peptide-I was added to the culture media at a concentration of $25~\mu\text{M}$, the cells were fixed 24 hours later, and then analysed by fluorescence-activated cell sorting (FACS). G_1 -, S- and G_2 -phase distribution of untreated and Peptide-I treated cells was assayed using bromodeoxyuracil (BrdU). The number of cells entering S-phase in the presence of Peptide-I was dramatically reduced and the G_1 population showed a concomitant increase. This suggests that Peptide-I mimics the ability of full length $p21^{\text{WAF1}}$ to act as a growth suppressor by inducing a G_1 -cell cycle arrest.

In order to ascertain if Peptide-I was functioning as a growth inhibitor by preventing the phosphorylation of pRb in a manner analogues to p21^{WAF1}, we used serum starvation to produce a 25 synchronous population of HaCaT cells. Peptide-I was added to the cells at the same time as they were released from serum starvation and samples from treated and untreated cells were taken over a 24 hour period. The phosphorylation status of pRb

68

was monitored by a gel mobility shift assay. When serum was added to starved cells, pRb became hyperphosphylated between 12 and 15 hours, but in the presence of Peptide-I pRb remained hypophosphorylated. Thus, Peptide I causes a G₁-arrest in human 5 HaCaT cells by preventing the phosphorylation of pRb.

We took an identical experimental approach to introduce, (i) the bio-active truncated peptide 10 and (ii) a control peptide 10 which lacked essential residues for CDK inhibition, into HaCaT 10 cells. We found that Peptide-II effectively promoted a G_1 -phase arrest and totally prevented the phosphorylation of pRb when added at 50 μ M (Figure 9b). However Peptide-III, which lacked the last 4 amino acids of peptide 10 (LIFS) had no detectable effect on the ability of HaCaT cells to enter S-phase. It is 15 interesting that the truncated peptide 10 when coupled to carrier peptide (Peptide-II) and introduced into cells is only 2-fold less active as a growth suppressor than Peptide-I (see above for in vitro data). Linking the truncated peptide 10 to the carrier peptide may promote a more favourable inhibitory 20 conformation, as the $I_{0.5}$ for carrier linked truncated peptide 10 (Peptide-II in vitro is approximately 50-fold less than that of the free peptide 10 (data not shown).

Peptide 10 was added to Rb negative cells, and the results support its mimicry of the full length protein, i.e. it can mimic its biolgical activity as a cell cycle inhibitor. Peptide 10 was found to cause cell cycle arrestin pRb negative, as well as pRb positive cells. Using Soas2 cells the introduction of

69

peptide I (peptide 10 linked to penetratin and mutated to prevent PCNA binding) leads to an increase in the population of cells in G1 phase.

5 Discussion

Synthetic peptides or peptido-mimetics are proving to be useful in studying the biochemical regulation of enzymes and proteins, and also in providing models for the design of novel 10 anti-proliferative agents targeted to the enzymatic pathways amplified or proteins activated in human tumours (Powis, 1992; Gibbs and Oliff, 1994). Peptides which have been shown to effectively target components of the cell cycle machinery include: FTI, which inhibit farnesyl protein transferase 15 preventing the activation of Ras (Gibbs et al., 1994); Ras effector domain peptides, which can inhibit its biological function (Moodie and Wolfman, 1994; Rodriguez-Viciana et al., 1994); SH2/SH3 domain-harbouring polypeptides, which in theory should inhibit the growth of tumours with activated tyrosine 20 kinases (Pawson and Schlessinger, 1993; Yu et al., 1994), and pl6INK4-derived peptides, which inhibit cyclin D-CDK complex activity and thereby activate pRb-dependent cell cycle arrest (Fåhraeus et al., 1996).

25 Inactivation of the tumour suppressor protein p53 is a common event in the development of human neoplasia (Hollstein et al., 1991). The p53 protein is a key player in an inducible cell cycle checkpoint pathway activated in response to DNA-damage and

70

nucleotide pool perturbation (Lane, 1992; Agarwal et al., 1995). Reactivation of this pathway could therefore provide a route to the discovery of novel anti-proliferative drugs. A variety of mechanisms could lead to the functional inactivation of the p53 5 pathway, including the inactivation of downstream effector molecules of p53, such as the cyclin-kinase inhibitor p21WAF1 (Deng et al., 1995; Waldman et al., 1995). Recent developments have shown that reactivation of the p53 pathway in some human tumours may be possible by activating the biochemical function 10 of the endogenous mutant p53 protein (Halazonetis and Kandil, 1993; Hupp et al., 1993), possibly using small peptides as leads for drug design (Hupp et al., 1995) or by reintroducing the wild type p53 gene using adenovirus vectors (Eastham et al., 1995). However, in general, the pharmacological restoration of 15 biochemical function to a protein that has lost its normal activity through mutation of its amino acid sequence is more difficult than the inhibition of a biochemical function (Gibbs and Oliff, 1994). Thus, it may prove more productive to take alternative approaches to restore activity to the p53 pathway 20 such as mimicking the inhibitory activity of the downstream effector molecule p21WAF1, which can by itself mediate growth arrest primarily through its interaction with the G1 cyclin-CDKs (El-Deiry et al., 1993; Eastham et al., 1995; Harper et al., 1995).

25

Determining the minimal domain of p21WAF1 that can inhibit CDK function and whether such a domain can function in isolation with high efficiency are two important goals which must be

achieved in order to determine whether p21WAF1 will prove to be a realistic template for use in anti-proliferative drug design research. Prior to our studies, the minimal sequence of p21WAF1 shown to inhibit CDK function in vitro was the N-terminal domain 5 (residues 1-75) (Luo et al., 1995). Whilst peptides derived from this N-terminal domain have recently been shown to antagonise the ability of p21WAF1 to inhibit cyclin E-Cdk2 complex activity suggesting that this domain interacts with the kinase (Chen et al., 1996), no data on the direct interaction 10 of small peptides with either cyclin or CDK has previously been presented. In addition, no evidence existed to suggest that a small peptide derived from p21WAF1 would in fact be biologically active as a CDK inhibitor. As the cyclin D1-Cdk4 complexes and related isoforms are essential for progression through G1-phase, 15 we have used a series of small synthetic peptides based on the sequence of p21WAF1 to, (i) determine whether Cdk4 inhibitory peptide-mimetics exist and if they are of high efficacy, and (ii) probe the mechanism by which the p21WAF1 protein inhibits cyclin D1-Cdk4 activity.

20

A Model for the Inhibition of Cyclin D1-Cdk4 by p21WAF1
Two distinct peptides from the N-terminal domain of p21WAF1
interacted with either Cdk4 or cyclin D1 to form stable
complexes. One peptide bound to Cdk4 but did not inhibit its
25 activity, while the second bound specifically to cyclin D1 and
had potent inhibitory effects on cyclin D1-Cdk4 activity. The
Cdk4 binding peptide 4 (residues 46-65) corresponded to a
putative Cdk2 binding domain of p21WAF1 previously defined using

72

p21WAF1 deletion constructs (Nakanishi et al., 1995a) and alanine mutation analysis (Goubin and Ducommun, 1995). We have established that this region of p21WAF1 is, in fact, directly involved in CDK binding, yet it has no Cdk4 inhibitory activity (Figures 2 and 3). These data explain why certain N-terminally deleted p21WAF1 constructs, which still contain the CDK binding site, fail to efficiently inhibit cell growth (Nakanishi et al., 1995a).

10 The second N-terminal peptide, which bound to cyclin D1, potently inhibited cyclin D1-Cdk4 activity through a novel mechanism (see below). The mechanism of p21WAF1 inhibition of cyclin-CDK complexes is poorly understood, as it has not been clear whether p21WAF1 protein inhibits by cyclin and/or kinase 15 subunit binding. Cdk2 binds very weakly to p21WAF1 in the absence of cyclin, the affinity of the G1-CDKs for p21WAF1 being greatly increased if the CDK is associated with a cyclin (Harper et al., 1995), suggesting that cyclins play an important role in p21WAF1 inhibition of CDK activity. However, whether a 20 CKI, such as p21WAF1 and p27KIP1, can interact directly with cyclin is in dispute (Toyoshima and Hunter, 1994; Harper et al., 1995). A recent study however, suggested that p21WAF1 can interact directly with a number of cyclins in the absence of CDK (Fotedar et al., 1996). We show here that a small peptide 25 composed of residues 16-35 (peptide 2) forms a stable complex with cyclin D1 and that this peptide alone is a potent inhibitor of Cdk4 activity, with an $I_{0.5}$ of 2 mM. This peptide falls within the growth suppressor region (residues 17-71), described

73

by Nakanishi et al. (1995a). This is the first time that a putative cyclin binding site on p21^{WAF1} has been identified and that a small synthetic peptide representing this domain has been shown to be sufficient to mimic the full length p21^{WAF1} protein.

5 as a CDK inhibitor.

The fact that cyclin D1-Cdk4 activity can be inhibited by interaction with the cyclin subunit alone, suggests either (i) that conformational changes in cyclin D1 can lead to the 10 inhibition of Cdk4 catalytic activity, (ii) that peptide 2 interferes with the interaction of cyclin D1 with Cdk4 or (iii) that peptide 2 interferes with the interaction of cyclin D1-Cdk4 with its substrate pRb.

15 Prospects for the design of small molecular mimetics of p21WAF1 are more viable given that the cyclin D1-binding peptide alone can inhibit kinase function, indicating that the prior presence of one p21WAF1 protein binding to the kinase subunit is not required for inhibition of kinase function. In addition, the 20 amino acid residues that are conserved between p21WAF1 and its close relative p27KIP1 (Polyak et al., 1994; Toyoshima and Hunter, 1994) are clustered within the N-terminal domain, with the regions corresponding to peptides 2 (65% identical) and peptide 4 (50% identical) containing the majority of the 25 conserved amino acids. This suggests that inhibition of Cdk4 activity by interaction with the cyclin D subunit may be a common mechanism employed by both p21WAF1 and p27KIP1.

74

A Novel p21WAF1 C-Terminal Cyclin D1-Cdk4 Inhibitory Domain During the course of our studies we also found that a peptide (peptide 10) from the C-terminal domain of p21WAF1 was a potent inhibitor of cyclin D1-Cdk4 activity in vitro. The inhibitory 5 motif was identified and was distinct from the PCNA interacting site, which also resides in the C-terminal domain of p21WAF1 (Chen et al., 1995; Luo et al., 1995; Warbrick et al., 1995; Ball and Lane, 1996). Our results are in contrast to previous studies which have found that cyclin-Cdk2 inhibitory activity 10 is confined solely to the N-terminal domain of p21WAF1, when each half is expressed separately (Chen et al., 1995; Luo et al., 1995). The reasons for this discrepancy may include: (i) the use of C-terminally his-tagged p21WAF1 in vectors for purifying p21 WAF1 constructs (Luo et al., 1995), 15 which may have affected the local structure at the C-terminus of p21WAF1; (ii) the transfection of constructs containing only the C-terminal half of p21WAF1 (Chen et al., 1995; Luo et al., 1995) this may make folding into the correct native conformation difficult precluding identification of the novel inhibitory 20 domain; (iii) by using peptides, rather that the C-terminal constructs or full length p21WAF1 protein, we may have exposed sites which would not be solvent exposed in native full length p21WAF1 protein; (iv) it is possible that there may be subtle differences in the mechanism(s) used by p21WAF1 to inhibit 25 cyclin-Cdk2 complexes and cyclin D1-Cdk4. Whether, the C-terminal inhibitory motif defines a novel physiologically relevant regulatory site on p21WAF1 is currently being addressed. However, the potency of peptide 10 ($I_{0.5} = 0.1 \text{ mM}$,

75

only 10-fold lower than full length p21^{WAF1} protein in these assays) and its ability to completely inhibit cyclin D1-Cdk4, suggests to us that further studies on this region of full length p21^{WAF1} will be well worth pursuing.

5

Peptide 10 represents a potentially exciting lead for drug design as it is by far the most potent peptide inhibitor of CDK activity discovered to date, being > 150-fold better than the recently identified peptide mimetic of p16INK4 (Fahraeus et al., 1996) and 20-fold better than the N-terminal inhibitory p21WAF1-derived-peptide which we have described. The fact that the residues important for inhibitory activity are confined to a stretch of just five amino acids, suggests that contact at a single interface is sufficient to produce a highly potent inhibitor of the cyclin D1-Cdk4 activity, making this a realistic template for the design of small molecules which mimic p21WAF1 activity.

The fact that peptide 10 retains inhibitory activity when 20 reduced to just eight amino acids (KRRLIFSK) improves its appeal as a template for rational drug design. In general protein-protein interfaces are relatively large relying on the participation of between 10-30 contact side chains on each interface, with each region of contact often being composed of residues which are dispersed throughout the primary amino acid sequence (Davies et al, 1990; de Vos et al, 1992). However, there is evidence that in some cases only a small subset of these side chains need to be contacted for efficient binding to

76

occur (Kelley and O'connel, 1993, Cunningham and Wells, 1994; Clackson and Wells, 1995). The discovery that a single eight amino acid peptide is alone sufficient to inhibit the activity of a critical G₁-cyclin-CDK preventing pRb phosphorylation and 5 producing a G₁-cell cycle arrest in tissue culture cell systems, suggests that interaction at only a small subset of contact side chains is necessary for potent inhibition of cyclin D1-Cdk4 activity at the G1-S phase boundary. This makes cyclin D1-Cdk4 a realistic and exciting target for the design of small 10 synthetic compounds which can at act as anti-proliferative agents.

CLAIMS

 An assay method for identifying a compound with ability to modulate interaction or binding between p21 and cyclin D1 and/or
 Cdk 4, the method including:

- (a) bringing into contact p21 or a fragment thereof, cyclin D1 and/or Cdk4, or a fragment thereof, and a test compound, under conditions wherein, in the absence of the test compound being an inhibitor of interaction or binding of p21 and cyclin D1 and/or Cdk 4, the p21 or fragment thereof and the cyclin D1
 - and/or Cdk4 or fragment thereof interact or bind; and

 (b) determining interaction or binding between the p21 or fragment thereof and the cyclin D1 and/or Cdk 4 or fragment

thereof.

15

25

- 2. An assay method for identifying a compound with ability to modulate interaction or binding between p21 and cyclin D1 and/or Cdk 4, the method including:
- (a) bringing into contact a substance which includes p21 or a 20 peptide fragment thereof, or a derivative thereof, which is

RERWNFDFVTETPLEGDFAW (peptide 4)

KACRRLFGPVDSEQLSRDCD (peptide 2)

KxxRRyFzP (wherein x may be any amino acid, y and z
may be hydrophobic, and each of the
underlined residues may be absent or
different)

KRRQTSMTDFYHSKRRLIFS

KRRQTSATDFYHSKRRLIFS (peptide 10)

80

TSMTDFYHSKRRLIFSKRKP (peptide 11)

KRRLIFSK, or

xyLzF (wherein y and z are any amino acid and x is preferably R)

- 5 or a derivative, fragment or analogue of a said fragment, a substance including cyclin D1 and/or Cdk4, or a derivative or analogue thereof, and a test compound, under conditions wherein, in the absence of the test compound being an inhibitor of interaction or binding of said substances, said substances 10 interact or bind; and
 - (b) determining interaction or binding between said substances.
- 3. An assay method according to claim 1 or claim 2 wherein the fragment, derivative or analogue of p21 includes the amino acid 15 sequence of peptide 4.
 - 4. An assay method according to claim 1 or claim 2 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence $\underline{K}xxRRyFz\underline{P}$.

20

5. An assay method according to claim 4 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence of peptide 2.

25

6. An assay method according to claim 1 or claim 2 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence xyLzF.

- 7. An assay method according to claim 6 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence of peptide 10.
- 5 8. An assay method according to claim 6 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence KRRLIFSK.
- 9. An assay method according to claim 8 wherein the fragment,
- 10 derivative or analogue of p21 includes the amino acid sequence of peptide 11.
- 10. A method according to any of claims 1 to 9 wherein a compound is additionally tested for ability to modulate a p21-15 mediated effect on Cdk4 activity.
 - 11. A method according to claim 10 wherein the Cdk4 activity includes RB phosphorylation.
- 20 12. A method according to claim 10 wherein induction of G1 cell-cycle arrest is tested.
 - 13. A method of identifying a compound able to modulate a p21-mediated effect on Cdk4 activity, the method including:
- 25 (a) contacting cells with a test compound;
 - (b) determining modulation of the p21-mediated effect on Cdk4 activity in the cells;
 - (c) selecting a compound able to modulate the p21-mediated

WO 97/42222

effect on Cdk4 activity as determined in step (b).

- 14. A method according to claim 13 wherein ability of a compound able to modulate the p21-mediated effect on Cdk4 activity is also tested for ability to interfere with interaction and/or binding between p21 and cyclin D1 and/or Cdk4.
- 15. A method according to claim 13 or claim 14 wherein the Cdk4 10 activity includes RB phosphorylation.
 - 16. A method according to claim 13 or claim 14 wherein induction of G1 cell-cycle arrest is tested.
- 15 17. A method which includes, following identification of a compound as being able to interfere with interaction or binding between p21 and cyclin D1 and/or Cdk4 and/or modulate a p21-mediated effect on Cdk4 activity in accordance with any of claims 1 to 16, formulation of the compound into a composition including at least one additional component.
 - 18. Use of a substance which includes p21 or a peptide fragment thereof, or a derivative thereof, selected from

RERWNFDFVTETPLEGDFAW (peptide 4)

25 KACRRLFGPVDSEQLSRDCD (peptide 2)

KxxRRyFzP (wherein x may be any amino acid, y and z
may be hydrophobic, and each of the
underlined residues may be absent or

83

different)

KRRQTSMTDFYHSKRRLIFS

KRRQTSATDFYHSKRRLIFS (peptide 10)

TSMTDFYHSKRRLIFSKRKP (peptide 11)

5 KRRLIFSK, or

xyLzF (wherein y and z are any amino acid and x is preferably R)

or a derivative, fragment or analogue of a said fragment, able to interact with or bind cyclin D1 and/or Cdk4, in screening for compounds able to modulate interaction or binding between p21 and cyclin D1 and/or Cdk4

- 19. Use of a substance which includes p21 or a peptide fragment thereof, or a derivative thereof, selected from
- 15 RERWNFDFVTETPLEGDFAW (peptide 4)

KACRRLFGPVDSEQLSRDCD (peptide 2)

 $\underline{K}xxRRyFz\underline{P}$ (wherein x may be any amino acid, y and z

may be hydrophobic, and each of the

underlined residues may be absent or

20 different)

KRRQTSMTDFYHSKRRLIFS

KRRQTSATDFYHSKRRLIFS (peptide 10)

TSMTDFYHSKRRLIFSKRKP (peptide 11)

KRRLIFSK, or

25 xyLzF (wherein y and z are any amino acid and x is preferably R)

or a derivative, fragment or analogue of a said fragment, able to interact with or bind cyclin Dl and/or Cdk4, in screening for

84

compounds able to modulate a p21-mediated effect on Cdk4 activity.

- 20. Use according to claim 19 wherein the Cdk4 activity 5 includes RB phosphorylation.
 - 21. Use according to claim 18 wherein induction of G1 cell-cycle arrest is tested.
- 10 22. Use according to any of claims 18 to 21 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence of peptide 4.
- 23. Use according to any of claims 18 to 21 wherein the 15 fragment, derivative or analogue of p21 includes the amino acid sequence <u>KxxRRyFzP</u>.
- 24. Use according to claim 23 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence of peptide 20 2.
 - 25. Use according to any of claims 18 to 21 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence xyLzF.

25

26. Use according to claim 25 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence of peptide 10.

- 27. Use according to claim 25 wherein the fragment, derivative or analogue of p21 includes the amino acid sequence KRRLIFSK.
- 28. Use according to claim 27 wherein the fragment, derivative 5 or analogue of p21 includes the amino acid sequence of peptide 11.
- 29. A method of designing mimetics of p21 having the biological activity of Cdk4 binding or inhibition, the activity of 10 allosteric inhibition of Cdk4 and/or the activity of cyclin D1 binding, said method comprising:
 - (i) analysing a substance having the biological activity to determine the amino acid residues essential and important for the activity to define a pharmacophore; and
- (ii) modelling the pharmacophore to design and/or screen candidate mimetics having the biological activity.
- 30. A method which includes, following identification of a mimetic as having the biological activity of Cdk4 binding or 20 inhibition, the activity of allosteric inhibition of Cdk4 and/or the activity of cyclin Dl binding in accordance with claim 29, formulation of the mimetic into a composition including at least one additional component.
- 25 31. Use of a substance which comprises:
 - (i) a fragment of p21, or an active portion or derivative thereof;
 - (ii) a peptide fragment including the motif xyLzF, wherein

86

y and z are any amino acid and x is preferably R, or a derivative of said peptide fragment with the property of inhibiting Cdk4;

- (iii) a peptide fragment including the motif KxxRRyFzP,
 5 wherein x is any amino acid, y and z may be hydrophobic, and
 each of the underlined residues may be absent or different; or
 - (iii) a functional mimetic of (i), (ii) or (iii) with the
 property of inhibiting Cdk4;

in the manufacture of a medicament for inhibiting Cdk4, for the 10 treatment of a disorder mediated by Cdk4 activity, or for the treatment of a hyperproliferative disorder by inhibiting Cdk4.

32. Use according to claim 31 wherein the substance comprises or consists essentially of a peptide fragment with a sequence 15 which is

RERWNFDFVTETPLEGDFAW (peptide 4)

KACRRLFGPVDSEQLSRDCD (peptide 2)

KRRQTSMTDFYHSKRRLIFS

20 KRRQTSATDFYHSKRRLIFS (peptide 10)

TSMTDFYHSKRRLIFSKRKP (peptide 11)

or KRRLIFSK,

or a functional mimetic of any of these peptide sequences with the property of inhibiting Cdk4.

25

33. Use according to claim 32 wherein the substance consists essentially of the peptide KRRLIFSK or a functional mimetic thereof with the property of inhibiting Cdk4.

87

- 34. Use according to any of claims 31 to 33 wherein the substance is coupled to a carrier for delivery to cells.
- 35. Use according to claim 34 wherein the substance is a 5 peptide and is coupled to a carrier peptide with the sequence RQIKIWFQNRRMKWKK.
- 36. The peptide KRRLIFSK, or a functional mimetic thereof with the property of inhibiting Cdk4, for use in a method of 10 treatment of the human or animal body by therapy.
 - 37. The peptide or functional mimetic thereof according to claim 36 wherein the treatment is of a hyperproliferative disorder.

15

- 38. A method of interfering with interaction between p21 and cyclin D1 and/or Cdk4, the method including contacting p21 and/or Cdk4 with a substance which includes a peptide fragment of p21 or a derivative thereof which is
- 20 RERWNFDFVTETPLEGDFAW (peptide 4)
 KACRRLFGPVDSEQLSRDCD (peptide 2)

KxxRRyFzP (wherein x may be any amino acid, y and z may be hydrophobic, and each of the underlined residues may be absent or

| Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet) |
|--|
| This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons: |
| 1. X Claims Nos.: 31-35, 38-41 because they relate to subject matter not required to be searched by this Authority, namely: Remark: Although claim(s) 31-35, 38-41 is(are) directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition. 2. Claims Nos.: |
| because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically: |
| 3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a). |
| Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet) |
| This International Searching Authority found multiple inventions in this international application, as follows: |
| |
| 1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims. |
| 2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee. |
| 3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.: |
| A. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: |
| Remark on Protest The additional search fees were accompanied by the applicant's protest. No protest accompanied the payment of additional search fees. |

Human and plant proliferating-cell nuclear antigen have a highly conserved binding site for the p53-inducible gene product p21^{wAF1}

Kathryn L. BALL and David P. LANE

CRC Cell Transformation Group, Department of Biochemistry, Medical Sciences Institute, University of Dundee, UK

(Received 16 November 1995/13 February 1996) - EJB 95 1900/3

The mechanism(s) whereby higher plants respond to environmental agents that damage their DNA, which leads to the arrest of cell division, is poorly understood. In mammalian cells, the tumour-suppressor protein p53 plays a central role in a DNA-damage-induced cell-cycle-checkpoint pathway by induction of transcription of a set of gene products that have a direct role in a DNA-damage-induced cell-cycle growth arrest. One such protein, p21^{wAF1}, has been shown to be essential for radiation-induced growth arrest. There appear to be at least two cellular targets of p21 wart during checkpoint control, the G₁-cyclindependent kinases (CDK) and proliferating-cell nuclear antigen (PCNA). The aim of the research reported here was to determine whether the interactions between the human growth inhibitor p21 wari and PCNA from plants and humans are conserved. If so, this would suggest that modulation of PCNA activity may play an important role in plant responses to DNA damage and would imply that functional homologue(s) of p21 wafi exist in plants. We show that the p21 wafi-interaction domain of PCNA is conserved between humans and plants. A peptide that contains the site of human p21 waft that binds human PCNA has been used to precipitate PCNA from crude pea (Pisum savitum) extracts. We used the p21 wari peptide as an affinity matrix and showed that pea PCNA bound in a specific high-affinity manner. This finding was used to develop a purification protocol that allowed PCNA from plant tissue to be purified to homogeneity. Pure pea PCNA forms a stable complex with full-length human p21 wAP1 and the specific amino acids of p21 war required for the interaction have been identified. The critical residues were identical to those required for binding to human PCNA, which indicates that the interaction of human p21 waff with PCNA is highly conserved at each amino acid position between pea and human.

Keywords: proliferating-cell nuclear antigen; Pisum savitum; cell-cycle inhibitors; p21^{waF1}; peptide-affinity chromatography.

When plants are exposed to ultraviolet or ionising radiation, a broad spectrum of physical and chemical modifications of their DNA occur, which eventually leads to arrest of cell division (Mateos et al., 1992; Chagvardieff et al., 1989; Inoue and van Huystee, 1984). Studies have shown that plants possess mechanisms for repair of damaged DNA which include photoreactivation, excision repair (McLennan, 1988) and recombinational repair (Cerutti et al., 1992). Recently, information about some of the genes and proteins involved in these processes has emerged (Cerutti et al., 1992, 1993; Pang et al., 1993; Batschauer, 1993). For example, poly(ADP-ribose) polymerase has been identified in maize, wheat and pea nuclei (Chen et al., 1994). In mammalian systems, this enzyme functions when DNA is cleaved and rejoined during processes such as DNA repair, DNA recombination and gene rearrangement, and a role in detection of DNAstrand breaks has also been proposed (Althaus et al., 1992; de Murcia and Menissier-de Murcia, 1994). In addition, the discovery of ultraviolet-sensitive and X-ray-sensitive mutants should provide a valuable tool to identify other enzymes and proteins

involved in signalling and the response to genomic damage (Harlow et al., 1994; Britt et al., 1993; Davies et al., 1994). However, nothing is known about the signalling pathways that detect DNA damage and halt plant-cell division in response to environmental agents that affect genome integrity.

The response of mammalian cells to DNA-damaging agents such as ultraviolet and ionising radiation has been subject to much more intense investigation and is therefore better understood. The primary objective of a cell that has been subjected to DNA damage is to ensure that mutated DNA is not passed on to the next generation of cells as this could ultimately be disasterous for the organism. The mechanisms by which this is achieved are either to arrest the cell cycle at certain checkpoints, which allows repair to take place prior to DNA replication, or, if the level of chromosomal DNA damage exceeds the ability of the repair machinery to correct the lesions, the cell might undergo apoptosis or irreversible growth arrest. The tumour-suppressor protein p53 is central to the response of mammalian cells to radiation-induced DNA damage, as it is a key component in the pathways of cell-cycle arrest and apoptosis (reviewed by Lane, 1993). Although the events that lead from induction of p53 to apoptosis are not known, the role of p53 during cellcycle-checkpoint control is better understood. After exposure of cells to DNA-damaging radiation, the sequence-specific transcriptional activity of p53 increases, which leads to the induction

Abbreviations. PCNA, proliferating-cell nuclear antigen; CDK, cyclin-dependent kinase.

of a number of gene products implicated in growth control, including GADD45 (Kastan et al., 1992), mdm2 (Momand et al., 1992) and p21 WAF1 (El-Deiry et al., 1993). The biochemical activity of p21wafi is well defined and this protein is thought to coordinate cell-cycle arrest and DNA replication because it has been shown to be an inhibitor of cyclin-dependent kinases (CDK; Harper et al., 1993; Xiong et al., 1993; Strausfeld et al., 1994), a group of kinases that regulate cell-cycle progression (reviewed by Nigg, 1995), and of proliferating-cell nuclear antigen (PCNA; Waga et al., 1994), a polymerase δ processivity factor, which is an essential DNA-replication protein (Tan et al., 1986; Prelich et al., 1987a, b; Wold et al., 1989; Waga et al., 1994). The model of p21 wafi function is supported by the discovery that, although p21 wAF1-null mice are viable, p21 wAF1-null mouse-embryo fibroblasts are impaired in their ability to undergo cell-cycle arrest in G1 after exposure to ionising radiation (Brugarolas et al., 1995; Deng et al., 1995).

Little is known about the signalling pathways that lead to cell-cycle arrest after DNA damage in higher plants. Because we are interested in the conservation of checkpoint mechanisms between plants and mammals, the possible conservation of one key radiation-responsive pathway, the p53-dependent p21^{wAFI} signalling network, requires consideration. As one of the main targets of p21^{wAFI} is PCNA, biochemical characterisation of purified plant PCNA could lead to the identification of conserved domains implicated in the regulation of replication and cell-cycle checkpoints in plants. Such information would provide valuable information about the possible physiological functions of PCNA and could reveal the existence of factors that negatively regulate the plant cell cycle.

Although little is known about the structure/function relationships of plant PCNA, cDNAs that encode PCNA from several higher plants including rice and soybean (Suzuka et al., 1991) have been cloned and sequenced. Comparison of the coding regions of PCNA from rice and rat reveal 64% similarity at the nucleotide level and 62% similarity at the amino acid level. Furthermore, comparison of the predicted amino acid sequence of PCNA from soybean and rice indicate a high degree of similarity (88%; Suzuka et al., 1991). In addition to the presumed structural similarity between mammalian and plant PCNA there is also evidence for functional conservation. A recombinant fusion protein of rice PCNA and maltose-binding protein stimulated DNA synthesis catalysed by human polymerase δ (although less effectively than human PCNA), while it had no effect on polymerase α activity (Matsumoto et al., 1994). Similarly, calf thymus PCNA stimulates the activity and processivity of two DNA polymerases from wheat that appear to be polymerase- δ -like enzymes (Laquel et al., 1993). Thus, the functional interaction of plant PCNA and a key replicative DNA polymerase appears to be conserved between plants and animals. It is not known, however, whether the interaction of PCNA interaction with the cell-cycle-checkpoint-control machinery is conserved. Branch Strong Andrews

In this report, we develop an affinity matrix to purify PCNA from plants to homogeneity, and we show that the p21^{wAF1}-interaction site of PCNA is highly conserved between human and pea. The results are discussed in terms of the implication that a functional homologue of p21^{wAF1} exists in plants. The conservation of such a high-affinity interaction between PCNA and p21^{wAF1} in plants and animals, despite their distant evolutionary relationship, indicates that there has been a strong selection pressure to conserve this binding domain. It also provides biochemical evidence to suggest that higher plants may regulate radiation-induced cell-cycle checkpoints through modulation of PCNA activity by proteins that inhibit cell-cycle progression.

EXPERIMENTAL PROCEDURES

Reagents. Phenyl-Sepharose and the Mono-Q 5/5 HR column were obtained from Pharmacia and streptavidin-agarose was from Sigma. All peptides were synthesised by Chiron Mimotopes Peptide Systems by means of a multipin peptide-synthesis system. Each peptide had a biotin-SGSG spacer at the Cterminus and a free NH₂ at the N-terminus. Peptides were dissolved in dimethyl sulfoxide to approximately 5 mg/ml and stored at -70°C. The concentration of each peptide was accurately determined by amino acid analysis; each peptide was hydrolysed and the amino acids were derivatised with phenylisothiocyanate, then separated by HPLC. All other reagents were of the highest available commercial grade.

Plant material. Peas (*Pisum savitum v.* Onward) were grown in a greenhouse under natural-light conditions, and the seedlings were harvested by removal just below the cotyledons 10 d after germination and placed directly into extraction buffer at 4°C.

Peptide precipitation of PCNA. Peptide (1.5 μ g) was diluted in 100 μ l 146 mM NaCl, 14 mM sodium phosphate, pH 7.4, NaCl/P_i and incubated with 10 μ l packed streptavidinagarose beads for 1 h at room temperature. Unbound peptide was removed by extensive washing (four times with NaCl/P_i) and the beads with bound peptide were incubated for 1 h at 4°C with 20 μ l crude pea seedling extract that contained approximately 40 μ g total protein. The beads were washed three times with 1.5×NaCl/P_i and heated at 95°C for 4 min in the presence of 125 mM Tris/HCl, pH 6.8, 4% (mass/vol.) SDS, 20% (by vol.) glycerol and 200 mM dithiothreitol. Proteins were analysed by SDS/PAGE and Western blotting.

SDS/PAGE and Western blots. PCNA protein was detected after SDS/PAGE (Laemmli, 1970) by means of staining with Coomassie Brilliant Blue or silver stain, or after electrophoretic transfer onto nitrocellulose. Blots were blocked in 5% dried milk in NaCl/P, containing 0.1 % Tween 20 (NaCl/P,/Tween 20) for 1 h, washed in NaCl/P_i/Tween 20 and incubated with culture supernatant from PC10 (or other mAb)-secreting hybridomas for 1 h, washed with NaCl/P/Tween 20 and incubated for 1 h with horseradish-peroxidase-conjugated rabbit anti-mouse Ig (Dako) diluted 171000 in NaCl/P/Tween 20 containing 5% dried milk. In addition, a rabbit polyclonal antibody (3009, raised against a synthetic peptide that corresponded to the C-terminus of human PCNA) was used on Western blots of plant material. The 3009 serum was diluted 1:500 in NaCl/P;/Tween 20 containing 5% dried milk, and horseradish-peroxidase-congugated swine antirabbit Ig, diluted 1:1000 in NaCl/P,/Tween 20 containing 5% dried milk was used as secondary antibody. After removal of excess secondary antibody by washing with NaCl/P_i/Tween 20. bound protein was detected by enhanced-chemiluminescence (ECL) reaction and Hyperfilm-MP (Amersham).

Purification of PCNA from peas. All steps were carried out at 4°C. Extracts were prepared in a Waring blender by homogenisation of 200 g pea seedlings in 200 ml 50 mM Hepes, pH 8.0, 0.1 mM EDTA, 0.15 M NaCl, 1 mM benzamidine, 2 mM dithiothreitol and 0.1 mM phenylmethanesulfonyl fluoride. After addition of Triton X-100 to 1% (by vol.), the homogenate was centrifuged at $24\,000\times g$ for 20 min (the supernatant is referred to as the whole tissue extract). Ammonium sulfate was added to the supernatant to 40% saturation. The suspension was stirred for 20 min and the precipitate was collected by centrifugation at $24\,000\times g$ for 15 min. The pellet was discarded and ammonium sulfate was added to the supernatant to 60% saturation. This suspension was stirred for 20 min and the precipitate was collected as described above. The precipitate was dissolved in 50 mM Hepes, pH 7.4, 0.1 mM EDTA, 1 mM benz-

amidine, 2 mM dithiothreitol, 0.1 mM phenylmethanesulfonyl fluoride (buffer A) containing 1 M ammonium sulfate and applied to a 50-ml phenyl-Sepharose column equilibrated in buffer A plus 1 M ammonium sulfate. The column was washed with 200 ml buffer A plus 1 M ammonium sulfate, and proteins were eluted with a linear gradient from of 1 M to 0 M ammonium sulfate in buffer A over 500 ml. Fractions that were determined by Western blot analysis to contain PCNA were pooled and dialysed twice against 1 l 25 mM Hepes, pH 7.4, 0.1 mM EDTA, 0.1 M NaCl, 1 mM benzaminine, 2 mM dithiothreitol, 0.1 mM phenylmethanesulfonyl fluoride, 0.1% (by vol.) Triton X-100, 15% (by vol.) glycerol (buffer B). The dialysed protein was applied to a 2-ml peptide-10 affinity column equilibrated in buffer B, the column was washed with 12 ml buffer B containing 0.2 M NaCl and proteins were eluted with 12 ml buffer B containing 0.75 M NaCl. The peptide resin was made by incubation of 2 ml packed streptavidin-agarose beads with 300 µg peptide 10 overnight at 4°C with stirring. The column was poured and any unbound peptide was removed by extensive washing with NaCl/P_i. A 1-ml peptide column was used to determine binding of proteins from whole tissue extracts as described in the legend to Fig. 4. Fractions that contained PCNA were pooled, dialysed twice against 1 l buffer B, and the dialysed protein was applied to a MonoO 5/5 HR column equilibrated in buffer B. The protein was eluted with a linear gradient from 0.1 M to 1.0 M NaCl in buffer B over 30 ml. Fractions that contained PCNA were pooled, concentrated to 250 μg/ml, frozen and stored at -70°C.

Immunoprecipitation. Extracts of Escherichia coli that expressed recombinant human p21waF1 were prepared by lysis of cells in 50 mM Hepes, pH 8.0, 20% sucrose, 0.2 M KCl, 2 mM dithiothreitol, 1 mM benzamidine and 0.35 mg/ml lysozyme for 20 min at 4°C. The lysate was centrifuged at 14000×g for 20 min and the supernatant, which contained soluble p21WAF1, was used in immunoprecipitation assays. Pure pea PCNA (1 µg) was incubated with 20 µl E. coli extract and 100 µl of NaCl/P/ Tween 20 containing 0.1 mM phenylmethyane sulfonyl fluoride for 1 h at 4°C. A mAb (2 μg) that specifically recognises and immunoprecipitates p21 WAF1-Ab1; Oncogene Sciences) was added and the incubation was continued overnight. The protein · antibody complex was precipitated by addition of 10 µl (packed volume) protein-G beads, washed three times with NaCl/P_i/Tween 20 and incubated for 1 h. The beads were washed with 4×NaCl/P_i/Tween 20 and the bound proteins were removed by addition of sample buffer and incubation at 95°C for 5 min. The absence or presence of pea PCNA in the p21 WAF1 · antibody immune complex was determined by SDS/PAGE followed by Western blot analysis with PC10 as described above.

RESULTS

Monoclonal and polyclonal antibodies against mammalian PCNA can be used to detect denatured plant PCNA. Determination of conserved structural motifs in PCNA may provide valuable information on its regulation. We determined whether mAbs (PC2, PC5, PC8 and PC10) generated to rat PCNA by Waseem and Lane (1990) could recognise a protein from whole plant extracts by Western blot analysis. These antibodies have previously been shown to recognise HeLa, yeast (Schizosaccharomyces pombe) and insect (Spodoptera frugiperda) PCNA by denaturing immunoblot analysis (Waseem and Lane, 1990). However, the PC antibodies do not recognise denatured PCNA derived from Saccharomyces cerevisiae by Western blot analysis, which indicates that not all species retain the PC-type epitopes. Mapping of this antibody series by means of peptides derived from PCNA has established that the antibodies recognise

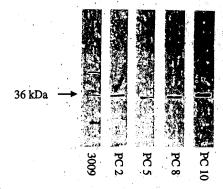

Fig. 1. Antibodies raised to mammalian PCNA recognise plant PCNA. Whole tissue extracts of pea were separated by SDS/PAGE, transferred to nitrocellulose and probed with mAbs PC2, PC5, PC8 and PC10 and the polyclonal antibody 3009. The position of PCNA (36 kDa) is indicated.

a region of PCNA between amino acids 111 and 120 (Cox, L. S. and Lane, D. P., unpublished results) described as the immunodominant region.

Since the PC antibodies recognise a highly conserved domain of mammalian PCNA, they were used to determine whether PCNA from plant lysates also contained this domain. mAbs PC2, PC5, PC8 and PC10 recognised a single polypeptide from denatured pea extracts with an apparent molecular mass of approximately 36 kDa (Fig. 1). This is in agreement with the apparent molecular mass of rice and soybean PCNA determined by SDS/PAGE (Suzuka et al., 1989; Daidoji et al., 1992). Although the amino acid sequence of pea PCNA is not known, the amino acid sequence of PCNA from several other higher plants has been deduced. Fig. 2A compares the sequences of plant PCNA with that of rat PCNA within the domain recognised by the PC series of antibodies. There is a high degree of crossspecies conservation and the amino acid substitutions are highly conservative. These results are consistent with the proposal that the 36-kDa protein from plant lysates detected with the PC antibodies is plant PCNA.

Because PC10 gave the strongest signal upon denaturing immunoblots of crude pea extracts, it was also tested to determine whether it could recognise native pea PCNA from crude lysates by means of an immunoprecipitation assay. PC10 did not immunoprecipitate PCNA from HeLa cell extracts or crude extracts of pea (data not shown). These results suggest that this epitope is not exposed in native human or pea PCNA. Strong support for this hypothesis has been supplied from the X-ray-crystallographic analysis of *E. coli* pol III subunit (Kong et al., 1992) and yeast PCNA (Krishna et al., 1994), where it appears that the S, D and L residues of the PC10 epitope are folded into a β sheet buried within the protein and are therefore not solvent exposed in the native protein.

In addition to the PC mAbs, a polyclonal antibody (3009), generated to a 15-amino-acid peptide (Cox, L. S. and Lane, D. P., unpublished result) that represents the C-terminus of human PCNA, could be used to detect pea PCNA by denaturing-immunoblot analysis (Fig. 1). This finding supports the conclusion that the 36-kDa protein detected immunochemically from pea lysates is PCNA. If the deduced amino acid sequences of plant PCNA are compared with the human C-terminal 15 residues, we find that the central region shows a high degree of identity, but there is some divergence in the C-terminus (Fig. 2). The ability to detect immunochemically a 36-kDa protein from pea lysates by means of mAbs and polyclonal antibodies specific for human PCNA has provided a biochemical assay to identify plant PCNA during purification and biochemical characterisation.

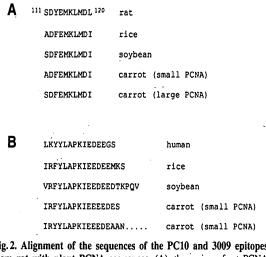

Fig. 2. Alignment of the sequences of the PC10 and 3009 epitopes from rat with plant PCNA sequences. (A), the region of rat PCNA that contains the PC10 epitope; (B), the sequence of the peptide, which corresponds to the C-terminus of human PCNA, that was used to raise the polyclonal antibody 3009. These sequences are compared with the deduced amino acid sequences of rice PCNA, soybean PCNA (Suzuka et al., 1991) and the small and large PCNA from carrot (Hata et al., 1992).

A p21^{wAF1} peptide can precipitate plant PCNA from whole tissue extracts. It has been shown that p21^{wAF1} can inhibit DNA through interaction with PCNA (Waga et al., 1994; Shivji et al., 1994) and evidence suggests that the physical binding of p21^{wAF1} to PCNA (Flores-Rozas et al., 1994) prevents PCNA functioning as a processivity factor for polymerase δ . The interaction site has been mapped by Warbrick et al. (1995), who found that a 20-amino-acid peptide (that corresponded to peptide 10 in our study; Fig. 3) bound to PCNA from HeLa cell extracts and lysates of *E. coli* that overexpressed human PCNA protein.

We used a set of overlapping peptides that span the entire sequence of p21^{wAF1} (Fig. 3) to identify peptides that can interact with PCNA from whole tissue extracts of pea seedlings. The p21^{wAF1} peptides were linked to biotin which allowed them to be attached to streptavidin-agarose beads. The peptide-linked beads were incubated with pea extracts and the protein bound to the beads was analysed by SDS/PAGE, blotted onto nitrocellulose, and probed with mAb PC10 (Fig. 3). Plant PCNA was precipitated by beads linked to peptide 10 (KRRQTSMTDFYHSKRR-LIFS). As PCNA from pea was not precipitated with peptide 11, which lacks the four N-terminal amino acids (KRRQ) of peptide 10, it appears that these residues are important for the interaction with pea PCNA.

PCNA could be quantitatively removed form pea extracts such that no PCNA remained in the supernatant as determined by Western blot analysis with PC10 (data not shown). These results indicate that there is only one biochemical form of PCNA in pea seedlings (i.e., non-p21^{wAF1}-binding fractions of pea PCNA are not detected) and that the interaction between PCNA and p21^{wAF1} peptide 10 is highly conserved between human and pea.

Binding of plant PCNA to a peptide-affinity column. To further define the avidity and specificity of the interaction between peptide 10 and PCNA from peas, we made a peptide-affinity column by biotinylated peptide 10 to streptavidin-agarose. When crude extracts of pea were applied to a 1-ml column in the presence of 0.1 M NaCl the majority of the protein (14 mg protein were applied to the column) flowed through (12.88 mg protein),

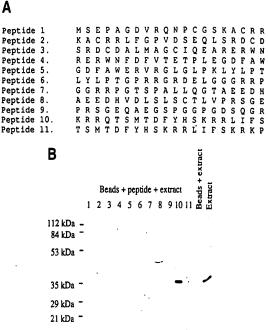

Fig. 3. Analysis of PCNA binding to p21^{wAF1} peptides. (A), peptides 1–11, which overlap, cover the entire protein sequence of p21^{wAF1} (B), each of the p21^{wAF1} peptides were attached to streptavidin-agarose beads and incubated with whole tissue extracts of pea. The proteins that remained on the beads after extensive washing were analysed by SDS/PAGE, transferred to nitrocellulose and probed with mAb PC10, followed by horseradish-peroxidase-anti-mouse secondary antibody and enhanced-chemiluminescent (ECL) detection. The positions of molecular-mass standards are indicated.

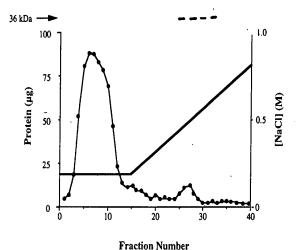

Fig. 4. Binding of plant PCNA to a peptide-affinity column. Whole tissue extracts of pea were applied to a 1-ml p21 waF1 peptide-10—affinity column and proteins were eluted with an NaCl gradient. (●), amount of protein. The elution of PCNA, detected by Western blots probed with PC10, is shown. The position of PCNA (36 kDa) is indicated.

but no PCNA was detected in this fraction. Fig. 4 shows that when the column was developed with a NaCl gradient the vast majority of protein, which bound non-specifically to the column, eluted at 0.2 M NaCl whereas PCNA was not eluted from the column until the concentration of NaCl was greater than 0.4 M. No PCNA bound to streptavidin-agarose beads that were not linked to peptide 10. This chromatographic method shows that PCNA binds specifically to p21^{wAFI} peptide 10 and elutes in one

Lane 1, pooled protein fractions after phenyl-Sepharose chromatography; lane 2, peptide-affinity-purified protein; lanes 3-5, purified protein after anion-exchange chromatography on MonoQ. The Western blot was probed with mAb PC10. The positions of molecular-mass standards are indicated.

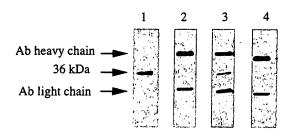

Fig. 6. Immunoprecipitation of human p21^{wAF1} and pea PCNA with p21^{wAF1}-specific antibody. Lane 1, Western blot of purified pea PCNA; lanes 2-4, immunoprecipitations followed by Western blots. Lane 2, control mAb specific for human p53; lane 3, p21^{wAF1}-specific mAb WAF1-Ab1 (Oncogene Sciences); lane 4, as lane 3, except that the pea PCNA was pre-incubated with peptide 10 and incubation with antibody was performed in the presence of peptide 10 (100 µg/ml). The Western blot was probed with the PCNA-specific mAb PC10.

peak, which provides evidence for only one biochemical form of PCNA in pea extracts, and that the interaction is of high affinity but can be disrupted by an increase of the ionic-strength of the buffer, which indicates that the interaction of PCNA with peptide 10 is reversible.

Purification of PCNA from whole pea extracts. The high-affinity interaction of PCNA with the peptide-affinity column was exploited when a purification protocol for pea PCNA was designed. Crude pea tissue extract was fractionated by means of ammonium sulfate precipitation, hydrophobic-interaction chromatography, peptide-affinity chromatography and anion-exchange chromatography on a MonoQ column. Recovery of PCNA from the peptide column was extremely high (approximately 95%), as judged by densitometry after Western blot analysis. 40 mg total protein were applied to the column and approximately 600 μg was eluted in the 0.75-M-salt wash, and therefore we estimate that PCNA was purified approximately 200-fold during this step. Peptide-affinity purification is a rarely

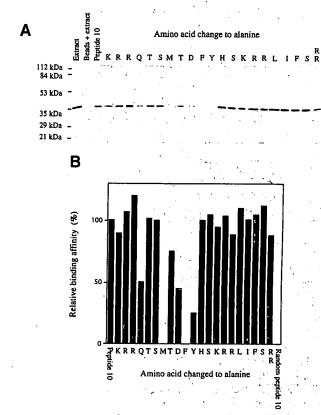

Fig. 7. Identification of the critical amino acid residues required for binding of plant PCNA to p21WAF1. The p21WAF1 residues that are critical for its interaction with pea PCNA were determined by generation of variants of peptide 10 in which each residue was sequentially changed to alanine. The ability of these peptides to interact with pea PCNA was determined by attachment of the peptides to streptavidine-agarose beads and incubation with whole tissue extracts of pea. Bound protein was analyzed by SDS/PAGE and Western blot analysis with PC10 to detect PCNA, as described in the legend for Fig. 3. (A), Western blot probed with PC10; (B), data expressed as relative binding affinity, where the binding of PCNA to each peptide has been standardised against the binding of PCNA to peptide 10, which is assumed to be 100%. These data were obtained by determination of the density of each band using a densitometer. The RR peptide had arginine residues 2 and 15 changed to alanine and the random peptide contained the same amino acids as peptide 10 but in a different order. -

used method of purification, but has been very successful in the purification of protein kinases (Woodgett, 1991).

The final preparation of pea PCNA, which eluted from the MonoQ column in approximately 0.4 M NaCl, was estimated to be greater than 98% pure by SDS/PAGE detected with Coomassie blue or silver stain (Fig. 5). The identity of the purified polypeptide was confirmed by transfer to nitrocellulose and immunochemical detection with PC10. PCNA from rice and soybean have previously been partially purified (Suzuka et al., 1989; Daidoji et al., 1992) but several major contaminating polypeptides were present in both those preparations. The method described here was also used to purify human PCNA (Ball, K. L. and Lane, D. P., unpublished results), which shows that the method is broadly applicable.

Interaction of plant PCNA with full-length human P21^{WAF1}. After we showed that pea PCNA could form a stable complex with p21^{WAF1} peptide 10, we needed to determine whether the pure pea PCNA could form a complex with full-length human p21^{WAF1}. When extracts from *E. coli* that expressed human

p21^{waF1} were mixed with pure pea PCNA in the presence of a p21^{waF1}-specific mAb, the isolated immune complex contained pea PCNA (Fig. 6). Formation of the complex was blocked if the PCNA was incubated with peptide 10. This finding indicates that the full-length human p21^{waF1} and the peptide can both form stable complexes with plant PCNA and that they compete for binding at the same site.

Critical residues for the interaction between plant PCNA and human p21wafi. Are residues that are critical for binding of p21 WAF1 to human PCNA also important for binding to pea PCNA? To define the critical residues involved in the binding of p21 wafi to pea PCNA we used a series of biotinylated peptides based on the sequence of peptide 10 in which each residue was changed sequentially to alanine (Fig. 7). Two other peptides were included in the analysis, a double substitution were two arginine residues were changed to alanine in the same peptide and a control peptide composed of the same residues as peptide 10 but in random order. We investigated the ability of the peptides linked to streptavidin-agarose to precipitate PCNA from pea extracts (as described above). Residues M and F were essential for binding as no PCNA was detected on Western blots if they were replaced with alanine (Fig. 7). Residue Y was also very important for binding, as only trace amounts of PCNA were detected when it was substituted, and mutations of Q and D considerably reduced the amount of PCNA precipitated. The random peptide did not precipitate any PCNA which suggests that it is the sequence and not just the presence of these amino acids that is of importance. Therefore, we are able to define the region of p21wafi involved in binding to pea PCNA as QTSMTDFY (residues underlined in bold are essential for binding, the Y in bold is extremely important for binding, and residues in italics contribute significantly to binding). These results are essentially identical to those found by Warbrick et al. (1995) for human PCNA. Thus, the binding site for p21^{waF1} on PCNA is highly conserved at each amino acid position between human and pea.

DISCUSSION

Although some key components of the cell-cycle regulatory machinery have been conserved during evolution, there is no generic cell cycle, and the relative importance of individual regulatory mechanisms depends on the organism under study. Our current knowledge of the cell cycle and checkpoint control is based mainly on information from yeast and mammalian tissueculture cells. It has become clear that the basic machinery for control of the cell cycle, namely the cyclin-dependent kinases and their regulatory subunits, the cyclins, are conserved between plants and other eukaryotes (reviewed by Staiger and Doonan. 1993). Several proteins involved in cell-cycle progression, including Cdc2 homologues (Feiler and Jacobs, 1990; Ferreira et al., 1991; Hirt et al., 1991) and G1 and G2 cyclins (Hata et al., 1991; Hemerly et al., 1992; Soni et al., 1995) have been identified in plants, and there is evidence for conservation of other regulators (Soni et al., 1995; Xie et al., 1995). Nothing, however, is known about the mechanism(s) of negative cell-cycle regulation and the possible existence of CDK-inhibitory or PCNA-inhibitory factors in plants. The first cell-cycle inhibitors were identified in yeast (Mendenhall, 1993; Schwob et al., 1994; Moreno and Nurse, 1994) and subsequently two groups (p21/KIP and INK4) of cell-cycle inhibitors were identified in mammalian cells (Sherr and Roberts, 1995), which are structurally unrelated to their yeast counterparts. The mammalian cellcycle inhibitors respond to a variety of negative growth signals

but, as described above, p21^{wAFI} is induced by the p53-mediated response generated by radiation-induced DNA damage. Our results suggest that a p21^{wAFI}-like protein exists in plants and that such a protein could modulate PCNA and, perhaps, cyclin-CDK activity during cell-cycle arrest.

PCNA is a component of the polymerase δ holoenzyme complex which acts as a processivity factor for polymerase δ , and as such is involved in leading-strand and lagging-strand synthesis during DNA replication (reviewed by Waga and Stillman, 1994). PCNA is also essential for nucleotide-excision repair (Shivji et al., 1992) which requires synthesis of new DNA after excision of the damaged stretch of DNA. Intense interest in PCNA and its function(s) was generated when PCNA was shown to be a component of cyclin-dependent kinase quaternary complexes (Xiong et al., 1992), which also contained cyclin-CDK and p21 WAFI. Although the functional relevance of this association is not known, it led to the discovery that p21 wafi inhibited DNA synthesis via a direct effect on PCNA (Waga et al., 1994; Flores-Rozas et al., 1994). Thus, PCNA not only interacts with components of the DNA-replication apparatus, it also interacts directly with a component of a cell-cycle-checkpoint pathway. While p21 war1 seems to inhibit DNA synthesis during replication it does not prevent the DNA synthesis that is required for repair (Flores-Rozas et al., 1994; Li et al., 1994; Strausfeld et al., 1994). The interaction between p21 waft and PCNA has been mapped by Warbrick et al. (1995), who found that a 20amino-acid peptide from the C-terminus of p21 bound to human PCNA and that this peptide was sufficient to inhibit simian virus 40 DNA replication in vitro. These results have been confirmed by deletion/mutation analysis (Chen et al., 1995; Goubin and Ducommun, 1995)

We have presented data that suggests that the p21 wafi-responsive regulatory domain of PCNA is conserved between plants and animals. We used overlapping peptides that cover the entire sequence of human p21 waf1 to probe for a site on plant PCNA that binds to p21^{waF1} or a p21^{waF1}-like regulatory protein. One of the peptides (peptide 10) was able to interact with pea PCNA, and although the same peptide interacted with PCNA from HeLa cell extracts and lysates of E. coli that over-expressed human PCNA (Warbrick et al., 1995), the affinity and specificity were not determined. The interaction of p21wAP1 peptide 10 with pea PCNA is highly specific because greater than 99.5% of the total protein applied to a peptide-affinity column either does not interact with the column or interacts non-specifically with the resin and elutes with a low-salt wash. In contrast, all PCNA bound to the column and was only dissociated from it by NaCl concentrations in excess of 0.4 M. This finding indicates that the peptide · protein interaction is reversible and of very-high affinity. The peptide-affinity column gave a 200-fold purification of PCNA and allowed us to purify plant PCNA to homogeneity. Purification of intact native PCNA is essential to understand the biochemical functions of plant PCNA and studies are underway to characterise the activity of the pure pea protein in in vitro replication and repair assays.

We showed formation of a stable complex of pure pea PCNA with full-length human p21^{wAF1}. That the formation of this complex was prevented if PCNA was incubated with peptide 10 implies that they compete for the same site on PCNA. Therefore pea PCNA can form a complex with full-length human p21^{wAF1} and the p21^{wAF1} mimetic, peptide 10. The amino acid residues that were critical for the interaction of plant PCNA with p21^{wAF1} were determined and were essentially identical to those important for binding to human PCNA (Warbrick et al., 1995). Thus, the interaction of p21^{wAF1} and PCNA is highly conserved at each amino acid position between plants and humans.

The results raise the possibility that there is a functional homologue of p21 wafi in higher plants, or that there is another protein, highly conserved during evolution, that interacts with PCNA from plant and animal sources with an identical specificity. Recent evidence also points to the existence in plants of a protein similar to retinoblastoma-protein in plants as its binding motif has been identified in a cyclin-D homologue from Arabidopsis thaliana (Soni et al., 1995) and in a protein from wheat geminivirus (Xie et al., 1995). The retinoblastoma protein is implicated in cell-cycle control as it is a substrate for the G₁-cyclin-CDK complexes and must be hyperphosphorylated for the cell cycle to proceed form G₁ into S phase (Weinberg, 1995). It seems probable that inhibition of PCNA and cyclin-CDK activity, which prevents replication and phosphorylation of key substrates such as retinoblastoma protein, is part of a checkpoint pathway, conserved between plants and animals, that leads to an arrest of the cell cycle. The factors that lead to activation of such a checkpoint pathway in plants are unknown. In mammalian cells, p53 is involved in detection of DNA damage. However, the p53 gene has only been found in the animal kingdom and more specifically in vertebrates (Soussi et al., 1990). Although p21 wari can be induced by other transcription factors (Jiang et al., 1994; Parker et al., 1995), p53-independent induction seems to be involved in senescence and differentiation rather than the damage response. It will therefore be of great interest to find out what induces a p21 was -like protein in plants, as it may give us new information about signal-transduction pathways that can lead to cell-cycle arrest after cellular damage. In addition, it would provide information about novel mechanisms that plants may have evolved to deal with DNA-damaging environmental stress, such as ultraviolet irradiation.

In conclusion, the identification of a p21^{waF1}-binding domain in PCNA derived from higher plants suggests a specific mechanism for modulation of PCNA activity. In addition, it suggests that cell-cycle inhibitors that can interact with PCNA and CDK during checkpoint control after DNA damage exist in higher plants. Future experiments will be aimed at the discovery of the protein(s) from plants that binds with high affinity to the p21^{waF1}-binding domain of pure pea PCNA, and the determination of the ability of such a protein to regulate PCNA and CDK activity.

We wish to thank Ted Hupp and Carol Midgley for critical reading of the manuscript. This work is funded by the Cancer Research Campaign. David Lane is a Gibb fellow of the Cancer Research Campaign and Howard Hughes International Scholar.
